Part I

Getting started

INSTALLATION

1.1 Conda installation

In order to install the Conda package, you will need to install Conda first. For a minimal conda installation (recommended) go to https://conda.io/miniconda.html. It is recommended that you always use the latest version of conda, as problems have been reported when trying to use older versions.

Once you have installed conda, you can install ESMValCore by running:

conda install -c esmvalgroup -c conda-forge esmvalcore

It is also possible to create a new Conda environment and install ESMValCore into it with a single command:

conda create --name esmvalcore -c esmvalgroup -c conda-forge esmvalcore

Don't forget to activate the newly created environment after the installation:

conda activate esmvalcore

Of course it is also possible to choose a different name than esmvalcore for the environment.

Note: Creating a new Conda environment is often much faster and more reliable than trying to update an existing Conda environment.

1.2 Pip installation

It is also possible to install ESMValCore from PyPI. However, this requires first installing dependencies that are not available on PyPI in some other way. By far the easiest way to install these dependencies is to use conda. For a minimal conda installation (recommended) go to https://conda.io/miniconda.html.

After installing Conda, download the file with the list of dependencies:

wget https://raw.githubusercontent.com/ESMValGroup/ESMValCore/master/environment.yml

and install these dependencies into a new conda environment with the command

conda env create --name esmvalcore --file environment.yml

Finally, activate the newly created environment

conda activate esmvalcore

and install ESMValCore as well as any remaining dependencies with the command:

pip install esmvalcore

1.3 Docker installation

ESMValCore is also provided through DockerHub in the form of docker containers. See https://docs.docker.com for more information about docker containers and how to run them.

You can get the latest release with

docker pull esmvalgroup/esmvalcore:stable

If you want to use the current master branch, use

docker pull esmvalgroup/esmvalcore:latest

To run a container using those images, use:

docker run esmvalgroup/esmvalcore:stable --help

Note that the container does not see the data or environmental variables available in the host by default. You can make data available with -v /path:/path/in/container and environmental variables with -e VARNAME.

For example, the following command would run a recipe

```
docker run -e HOME -v "$HOME":"$HOME" -v /data:/data esmvalgroup/esmvalcore:stable -c_
→~/config-user.yml ~/recipes/recipe_example.yml
```

with the environmental variable \$HOME available inside the container and the data in the directories \$HOME and /data, so these can be used to find the configuration file, recipe, and data.

It might be useful to define a bash alias or script to abbreviate the above command, for example

```
alias esmvaltool="docker run -e HOME -v $HOME:$HOME -v /data:/data esmvalgroup/

↔esmvalcore:stable"
```

would allow using the esmvaltool command without even noticing that the tool is running inside a Docker container.

1.4 Singularity installation

Docker is usually forbidden in clusters due to security reasons. However, there is a more secure alternative to run containers that is usually available on them: Singularity.

Singularity can use docker containers directly from DockerHub with the following command

Note that the container does not see the data available in the host by default. You can make host data available with -B /path:/path/in/container.

It might be useful to define a bash alias or script to abbreviate the above command, for example

```
alias esmvaltool="singularity run -B $HOME:$HOME -B /data:/data docker://esmvalgroup/

↔esmvalcore:stable"
```

would allow using the esmvaltool command without even noticing that the tool is running inside a Singularity container.

Some clusters may not allow to connect to external services, in those cases you can first create a singularity image locally:

singularity build esmvalcore.sif docker://esmvalgroup/esmvalcore:stable

and then upload the image file esmvalcore.sif to the cluster. To run the container using the image file esmvalcore.sif use:

singularity run esmvalcore.sif -c ~/config-user.yml ~/recipes/recipe_example.yml

1.5 Development installation

To install from source for development, follow these instructions.

- Download and install conda (this should be done even if the system in use already has a preinstalled version of conda, as problems have been reported with using older versions of conda)
- To make the conda command available, add source <prefix>/etc/profile.d/conda.sh to your .bashrc file and restart your shell. If using (t)csh shell, add source <prefix>/etc/profile.d/ conda.csh to your .cshrc/.tcshrc file instead.
- Update conda: conda update -y conda
- Clone the ESMValCore Git repository: git clone git@github.com:ESMValGroup/ESMValCore
- Go to the source code directory: cd ESMValCore
- Create the esmvalcore conda environment conda env create --name esmvalcore --file environment.yml
- Activate the esmvalcore environment: conda activate esmvalcore
- Install in development mode: pip install -e '.[develop]'. If you are installing behind a proxy that does not trust the usual pip-urls you can declare them with the option --trusted-host, e.g. pip install --trusted-host=pypi.python.org --trusted-host=pypi.org --trusted-host=files.pythonhosted.org -e .[develop]
- Test that your installation was successful by running esmvaltool -h.

CONFIGURATION FILES

2.1 Overview

There are several configuration files in ESMValCore:

- config-user.yml: sets a number of user-specific options like desired graphical output format, root paths to data, etc.;
- config-developer.yml: sets a number of standardized file-naming and paths to data formatting;
- config-logging.yml: stores information on logging.

and one configuration file which is distributed with ESMValTool:

• config-references.yml: stores information on diagnostic and recipe authors and scientific journals references;

2.2 User configuration file

The config-user.yml configuration file contains all the global level information needed by ESMValTool. It can be reused as many times the user needs to before changing any of the options stored in it. This file is essentially the gateway between the user and the machine-specific instructions to esmvaltool. By default, esmvaltool looks for it in the home directory, inside the .esmvaltool folder.

Users can get a copy of this file with default values by running

esmvaltool config get-config-user --path=\${TARGET_FOLDER}

If the option --path is omitted, the file will be created in $\$ (HOME)/.esmvaltool

The following shows the default settings from the config-user.yml file with explanations in a commented line above each option:

```
# Diagnostics create plots? [true]/false
# turning it off will turn off graphical output from diagnostic
write_plots: true
# Diagnostics write NetCDF files? [true]/false
# turning it off will turn off netCDF output from diagnostic
write_netcdf: true
# Set the console log level debug, [info], warning, error
# for much more information printed to screen set log_level: debug
```

(continues on next page)

log level: info

(continued from previous page)

```
# Exit on warning (only for NCL diagnostic scripts)? true/[false]
exit_on_warning: false
# Plot file format? [png]/pdf/ps/eps/epsi
output_file_type: png
# Destination directory where all output will be written
# including log files and performance stats
output_dir: ./esmvaltool_output
# Auxiliary data directory (used for some additional datasets)
# this is where e.g. files can be downloaded to by a download
# script embedded in the diagnostic
auxiliary_data_dir: ./auxiliary_data
# Use netCDF compression true/[false]
compress_netcdf: false
# Save intermediary cubes in the preprocessor true/[false]
# set to true will save the output cube from each preprocessing step
# these files are numbered according to the preprocessing order
save_intermediary_cubes: false
# Remove the preproc dir if all fine
# if this option is set to "true", ALL preprocessor files will be removed
# CAUTION when using: if you need those files, set it to false
remove_preproc_dir: true
# Run at most this many tasks in parallel [null]/1/2/3/4/..
# Set to null to use the number of available CPUs.
# If you run out of memory, try setting max_parallel_tasks to 1 and check the
# amount of memory you need for that by inspecting the file
# run/resource_usage.txt in the output directory. Using the number there you
# can increase the number of parallel tasks again to a reasonable number for
# the amount of memory available in your system.
max_parallel_tasks: null
# Path to custom config-developer file, to customise project configurations.
# See config-developer.yml for an example. Set to None to use the default
config developer file: null
# Use a profiling tool for the diagnostic run [false]/true
# A profiler tells you which functions in your code take most time to run.
# For this purpose we use vprof, see below for notes
# Only available for Python diagnostics
profile_diagnostic: false
# Rootpaths to the data from different projects (lists are also possible)
rootpath:
 CMIP5: [~/cmip5_inputpath1, ~/cmip5_inputpath2]
 OBS: ~/obs_inputpath
 default: ~/default_inputpath
# Directory structure for input data: [default]/BADC/DKRZ/ETHZ/etc
# See config-developer.yml for definitions.
```

(continues on next page)

(continued from previous page)

drs: CMIP5: default

Most of these settings are fairly self-explanatory, e.g.:

```
# Diagnostics create plots? [true]/false
write_plots: true
# Diagnostics write NetCDF files? [true]/false
write_netcdf: true
```

The write_plots setting is used to inform ESMValTool diagnostics about your preference for creating figures. Similarly, the write_netcdf setting is a boolean which turns on or off the writing of netCDF files by the diagnostic scripts.

```
# Auxiliary data directory (used for some additional datasets)
auxiliary_data_dir: ~/auxiliary_data
```

The auxiliary_data_dir setting is the path to place any required additional auxiliary data files. This is necessary because certain Python toolkits, such as cartopy, will attempt to download data files at run time, typically geographic data files such as coastlines or land surface maps. This can fail if the machine does not have access to the wider internet. This location allows the user to specify where to find such files if they can not be downloaded at runtime.

Warning: This setting is not for model or observational datasets, rather it is for data files used in plotting such as coastline descriptions and so on.

The profile_diagnostic setting triggers profiling of Python diagnostics, this will tell you which functions in the diagnostic took most time to run. For this purpose we use vprof. For each diagnostic script in the recipe, the profiler writes a .json file that can be used to plot a flame graph of the profiling information by running

vprof --input-file esmvaltool_output/recipe_output/run/diagnostic/script/profile.json

Note that it is also possible to use vprof to understand other resources used while running the diagnostic, including execution time of different code blocks and memory usage.

A detailed explanation of the data finding-related sections of the config-user.yml (rootpath and drs) is presented in the *Data retrieval* section. This section relates directly to the data finding capabilities of ESMValTool and are very important to be understood by the user.

Note: You can choose your config-user.yml file at run time, so you could have several of them available with different purposes. One for a formalised run, another for debugging, etc. You can even provide any config user value as a run flag --argument_name argument_value

2.3 Developer configuration file

Most users and diagnostic developers will not need to change this file, but it may be useful to understand its content. It will be installed along with ESMValCore and can also be viewed on GitHub: esmvalcore/config-developer.yml. This configuration file describes the file system structure and CMOR tables for several key projects (CMIP6, CMIP5, obs4mips, OBS6, OBS) on several key machines (e.g. BADC, CP4CDS, DKRZ, ETHZ, SMHI, BSC). CMIP data is stored as part of the Earth System Grid Federation (ESGF) and the standards for file naming and paths to files are set out by CMOR and DRS. For a detailed description of these standards and their adoption in ESMValCore, we refer the user to *CMIP data - CMOR Data Reference Syntax (DRS) and the ESGF* section where we relate these standards to the data retrieval mechanism of the ESMValCore.

By default, esmvaltool looks for it in the home directory, inside the '.esmvaltool' folder.

Users can get a copy of this file with default values by running

```
esmvaltool config get-config-developer --path=${TARGET_FOLDER}
```

If the option --path is omitted, the file will be created in `\${HOME}/.esmvaltool.

Note: Remember to change your config-user file if you want to use a custom config-developer.

Example of the CMIP6 project configuration:

```
CMIP6:
input_dir:
default: '/'
BADC: '{activity}/{institute}/{dataset}/{exp}/{ensemble}/{mip}/{short_name}/{grid}
↔/{latestversion}'
DKRZ: '{activity}/{institute}/{dataset}/{exp}/{ensemble}/{mip}/{short_name}/{grid}
↔/{latestversion}'
ETHZ: '{exp}/{mip}/{short_name}/{dataset}/{ensemble}/{grid}/'
input_file: '{short_name}_{mip}_{dataset}_{exp}_{ensemble}_{grid}*.nc'
output_file: '{project}_{dataset}_{mip}_{exp}_{ensemble}_{short_name}'
cmor_type: 'CMIP6'
cmor_strict: true
```

2.3.1 Input file paths

When looking for input files, the esmvaltool command provided by ESMValCore replaces the placeholders [item] in input_dir and input_file with the values supplied in the recipe. ESMValCore will try to automatically fill in the values for institute, frequency, and modeling_realm based on the information provided in the CMOR tables and/or config-developer.yml when reading the recipe. If this fails for some reason, these values can be provided in the recipe too.

The data directory structure of the CMIP projects is set up differently at each site. As an example, the CMIP6 directory path on BADC would be:

```
'{activity}/{institute}/{dataset}/{exp}/{ensemble}/{mip}/{short_name}/{grid}/
$\{\latestversion}\'
```

The resulting directory path would look something like this:

```
CMIP/MOHC/HadGEM3-GC31-LL/historical/r1i1p1f3/Omon/tos/gn/latest
```

For a more in-depth description of how to configure ESMValCore so it can find your data please see *CMIP data* - *CMOR Data Reference Syntax (DRS) and the ESGF*.

2.3.2 Preprocessor output files

The filename to use for preprocessed data is configured in a similar manner using output_file. Note that the extension .nc (and if applicable, a start and end time) will automatically be appended to the filename.

2.3.3 CMOR table configuration

ESMValCore comes bundled with several CMOR tables, which are stored in the directory esmvalcore/cmor/tables. These are copies of the tables available from PCMDI.

There are four settings related to CMOR tables available:

- cmor_type: can be CMIP5 if the CMOR table is in the same format as the CMIP5 table or CMIP6 if the table is in the same format as the CMIP6 table.
- cmor_strict: if this is set to false, the CMOR table will be extended with variables from the esmvalcore/cmor/tables/custom directory and it is possible to use variables with a mip which is different from the MIP table in which they are defined.
- cmor_path: path to the CMOR table. Defaults to the value provided in cmor_type written in lower case.
- cmor_default_table_prefix: defaults to the value provided in cmor_type.

2.4 References configuration file

The config-references.yml file contains the list of ESMValTool diagnostic and recipe authors, references and projects. Each author, project and reference referred to in the documentation section of a recipe needs to be in this file in the relevant section.

For instance, the recipe _ocean_example.yml file contains the following documentation section:

```
documentation:
  authors:
    - demo_le
  maintainer:
    - demo_le
  references:
    - demora2018gmd
  projects:
    - ukesm
```

These four items here are named people, references and projects listed in the config-references.yml file.

2.5 Logging configuration file

Warning: Section to be added

THREE

FINDING DATA

3.1 Overview

Data discovery and retrieval is the first step in any evaluation process; ESMValTool uses a *semi-automated* data finding mechanism with inputs from both the user configuration file and the recipe file: this means that the user will have to provide the tool with a set of parameters related to the data needed and once these parameters have been provided, the tool will automatically find the right data. We will detail below the data finding and retrieval process and the input the user needs to specify, giving examples on how to use the data finding routine under different scenarios.

3.2 CMIP data - CMOR Data Reference Syntax (DRS) and the ESGF

CMIP data is widely available via the Earth System Grid Federation (ESGF) and is accessible to users either via download from the ESGF portal or through the ESGF data nodes hosted by large computing facilities (like CEDA-Jasmin, DKRZ, etc). This data adheres to, among other standards, the DRS and Controlled Vocabulary standard for naming files and structured paths; the DRS ensures that files and paths to them are named according to a standardized convention. Examples of this convention, also used by ESMValTool for file discovery and data retrieval, include:

- CMIP6 file: [variable_short_name]_[mip]_[dataset_name]_[experiment]_[ensemble]_[grid]_[stanc
- CMIP5 file: [variable_short_name]_[mip]_[dataset_name]_[experiment]_[ensemble]_[start-date nc
- OBS file: [project]_[dataset_name]_[type]_[version]_[mip]_[short_name]_[start-date]-[end-onc

Similar standards exist for the standard paths (input directories); for the ESGF data nodes, these paths differ slightly, for example:

- CMIP6 path for BADC: ROOT-BADC/[institute]/[dataset_name]/[experiment]/ [ensemble]/[mip]/ [variable_short_name]/[grid];
- CMIP6 path for ETHZ: ROOT-ETHZ/[experiment]/[mip]/[variable_short_name]/ [dataset_name]/[ensemble]/[grid]

From the ESMValTool user perspective the number of data input parameters is optimized to allow for ease of use. We detail this procedure in the next section.

3.3 Data retrieval

Data retrieval in ESMValTool has two main aspects from the user's point of view:

- data can be found by the tool, subject to availability on disk;
- it is the user's responsibility to set the correct data retrieval parameters;

The first point is self-explanatory: if the user runs the tool on a machine that has access to a data repository or multiple data repositories, then ESMValTool will look for and find the available data requested by the user.

The second point underlines the fact that the user has full control over what type and the amount of data is needed for the analyses. Setting the data retrieval parameters is explained below.

3.3.1 Setting the correct root paths

The first step towards providing ESMValTool the correct set of parameters for data retrieval is setting the root paths to the data. This is done in the user configuration file config-user.yml. The two sections where the user will set the paths are rootpath and drs. rootpath contains pointers to CMIP, OBS, default and RAWOBS root paths; drs sets the type of directory structure the root paths are structured by. It is important to first discuss the drs parameter: as we've seen in the previous section, the DRS as a standard is used for both file naming conventions and for directory structures.

3.3.2 Explaining config-user/drs: CMIP5: Or config-user/drs: CMIP6:

Whereas ESMValTool will **always** use the CMOR standard for file naming (please refer above), by setting the drs parameter the user tells the tool what type of root paths they need the data from, e.g.:

drs: CMIP6: BADC

will tell the tool that the user needs data from a repository structured according to the BADC DRS structure, i.e.:

```
ROOT/[institute]/[dataset_name]/[experiment]/[ensemble]/[mip]/
[variable_short_name]/[grid];
```

setting the ROOT parameter is explained below. This is a strictly-structured repository tree and if there are any sort of irregularities (e.g. there is no [mip] directory) the data will not be found! BADC can be replaced with DKRZ or ETHZ depending on the existing ROOT directory structure. The snippet

```
drs:
   CMIP6: default
```

is another way to retrieve data from a ROOT directory that has no DRS-like structure; default indicates that the data lies in a directory that contains all the files without any structure.

Note: When using CMIP6: default or CMIP5: default it is important to remember that all the needed files must be in the same top-level directory set by default (see below how to set default).

3.3.3 Explaining config-user/rootpath:

rootpath identifies the root directory for different data types (ROOT as we used it above):

• CMIP e.g. CMIP5 or CMIP6: this is the *root* path(s) to where the CMIP files are stored; it can be a single path or a list of paths; it can point to an ESGF node or it can point to a user private repository. Example for a CMIP5 root path pointing to the ESGF node on CEDA-Jasmin (formerly known as BADC):

```
CMIP5: /badc/cmip5/data/cmip5/output1
```

Example for a CMIP6 root path pointing to the ESGF node on CEDA-Jasmin:

CMIP6: /badc/cmip6/data/CMIP6/CMIP

Example for a mix of CMIP6 root path pointing to the ESGF node on CEDA-Jasmin and a user-specific data repository for extra data:

CMIP6: [/badc/cmip6/data/CMIP6/CMIP, /home/users/johndoe/cmip_data]

• OBS: this is the *root* path(s) to where the observational datasets are stored; again, this could be a single path or a list of paths, just like for CMIP data. Example for the OBS path for a large cache of observation datasets on CEDA-Jasmin:

OBS: /group_workspaces/jasmin4/esmeval/obsdata-v2

- default: this is the *root* path(s) to where files are stored without any DRS-like directory structure; in a nutshell, this is a single directory that should contain all the files needed by the run, without any sub-directory structure.
- RAWOBS: this is the *root* path(s) to where the raw observational data files are stored; this is used by cmorize_obs.

3.3.4 Dataset definitions in recipe

Once the correct paths have been established, ESMValTool collects the information on the specific datasets that are needed for the analysis. This information, together with the CMOR convention for naming files (see *CMOR-DRS*) will allow the tool to search and find the right files. The specific datasets are listed in any recipe, under either the datasets and/or additional_datasets sections, e.g.

```
datasets:
  - {dataset: HadGEM2-CC, project: CMIP5, exp: historical, ensemble: rlilp1, start_
  -year: 2001, end_year: 2004}
  - {dataset: UKESM1-0-LL, project: CMIP6, exp: historical, ensemble: rlilp1f2, grid:_
  -gn, start_year: 2004, end_year: 2014}
```

_data_finder will use this information to find data for all the variables specified in diagnostics/ variables.

3.4 Recap and example

Let us look at a practical example for a recap of the information above: suppose you are using a config-user.yml that has the following entries for data finding:

```
rootpath: # running on CEDA-Jasmin
CMIP6: /badc/cmip6/data/CMIP6/CMIP
drs:
CMIP6: BADC # since you are on CEDA-Jasmin
```

and the dataset you need is specified in your recipe.yml as:

```
- {dataset: UKESM1-0-LL, project: CMIP6, mip: Amon, exp: historical, grid: gn,_

- ensemble: rli1p1f2, start_year: 2004, end_year: 2014}
```

for a variable, e.g.:

```
diagnostics:
    some_diagnostic:
    description: some_description
    variables:
        ta:
            preprocessor: some_preprocessor
```

The tool will then use the root path /badc/cmip6/data/CMIP6/CMIP and the dataset information and will assemble the full DRS path using information from *CMOR-DRS* and establish the path to the files as:

/badc/cmip6/data/CMIP6/CMIP/MOHC/UKESM1-0-LL/historical/r1i1p1f2/Amon

then look for variable ta and specifically the latest version of the data file:

/badc/cmip6/data/CMIP6/CMIP/MOHC/UKESM1-0-LL/historical/rli1p1f2/Amon/ta/gn/latest/

and finally, using the file naming definition from *CMOR-DRS* find the file:

```
/badc/cmip6/data/CMIP6/CMIP/MOHC/UKESM1-0-LL/historical/r1i1p1f2/Amon/ta/gn/latest/ta_

→Amon_UKESM1-0-LL_historical_r1i1p1f2_gn_195001-201412.nc
```

3.5 Observational data

Observational data is retrieved in the same manner as CMIP data, for example using the OBS root path set to:

```
OBS: /group_workspaces/jasmin4/esmeval/obsdata-v2
```

and the dataset:

```
- {dataset: ERA-Interim, project: OBS, type: reanaly, version: 1, start_

-year: 2014, end_year: 2015, tier: 3}
```

in recipe.yml in datasets or additional_datasets, the rules set in *CMOR-DRS* are used again and the file will be automatically found:

Since observational data are organized in Tiers depending on their level of public availability, the default directory must be structured accordingly with sub-directories TierX (Tier1, Tier2 or Tier3), even when drs: default.

3.6 Data loading

Data loading is done using the data load functionality of *iris*; we will not go into too much detail about this since we can point the user to the specific functionality here but we will underline that the initial loading is done by adhering to the CF Conventions that *iris* operates by as well (see CF Conventions Document and the search page for CF standard names).

3.7 Data concatenation from multiple sources

Oftentimes data retrieving results in assembling a continuous data stream from multiple files or even, multiple experiments. The internal mechanism through which the assembly is done is via cube concatenation. One peculiarity of iris concatenation (see iris cube concatenation) is that it doesn't allow for concatenating time-overlapping cubes; this case is rather frequent with data from models overlapping in time, and is accounted for by a function that performs a flexible concatenation between two cubes, depending on the particular setup:

- cubes overlap in time: resulting cube is made up of the overlapping data plus left and right hand sides on each side of the overlapping data; note that in the case of the cubes coming from different experiments the resulting concatenated cube will have composite data made up from multiple experiments: assume [cube1: exp1, cube2: exp2] and cube1 starts before cube2, and cube2 finishes after cube1, then the concatenated cube will be made up of cube2: exp2 plus the section of cube1: exp1 that contains data not provided in cube2: exp2;
- cubes don't overlap in time: data from the two cubes is bolted together;

Note that two cube concatenation is the base operation of an iterative process of reducing multiple cubes from multiple data segments via cube concatenation is if there is no time-overlapping data, the cubes concatenation is performed in one step.

WORKING WITH THE INSTALLED RECIPES

Although ESMValTool can be used just to simplify the managment of data and the creation of your own analysis code, one of its main strenghts is the continuosly growing set of diagnostics and metrics that it directly provides to the user. These metrics and diagnostics are provided as a set of preconfigured recipes that users can run or customize for their own analysis. The latest list of available recipes can be found here.

In order to make the managmenent of these installed recipes easier, ESMValTool provides the recipes command group with utilities that help the users in discovering and customizing the provided recipes.

The first command in this group allows users to get the complete list of installed recipes printed to the console:

esmvaltool recipes list

If the user then wants to explore any one of this recipes, they can be printed using the following command

esmvaltool recipes show recipe_name.yml

And finally, to get a local copy that can then be cusotmized and run, users can use the following command

esmvaltool recipes get recipe_name.yml

RUNNING

The ESMValCore package provides the esmvaltool command line tool, which can be used to run a recipe.

To run a recipe, call esmvaltool run with the desired recipe:

esmvaltool run recipe_python.yml

If the configuration file is not in the default location ~/.esmvaltool/config-user.yml, you can pass its path explicitly:

esmvaltool run --config_file /path/to/config-user.yml recipe_python.yml

It is also possible to explicitly change values from the config file using flags:

esmvaltool run --argument_name argument_value recipe_python.yml

To control the strictness of the CMOR checker, use the flag --check_level:

esmvaltool run --check_level=relaxed recipe_python.yml

Possible values are:

- ignore: all errors will be reported as warnings
- *relaxed*: only fail if there are critical errors
- *default*: fail if there are any errors
- strict: fail if there are any warnings

To run a reduced version of the recipe, usually for testing purpose you can use

esmvaltool run --max_datasets=NDATASETS --max_years=NYEARS recipe_python.yml

In this case, the recipe will limit the number of datasets per variable to NDATASETS and the total amount of years loaded to NYEARS. They can also be used separately.

To run a recipe, even if some datasets are not available, use

esmvaltool run --skip_nonexistent=True recipe_python.yml

If Synda is installed (see http://prodiguer.github.io/synda/), it is possible to use it to automatically download the requested data from ESGF if it is not available locally:

esmvaltool run --synda_download=True recipe_python.yml

It is also possible to select only specific diagnostics to be run. To tun only one, just specify its name. To provide more than one diagnostic to filter use the syntax 'diag1 diag2/script1' or '("diag1", "diag2/script1")' and pay attention to the quotes.

esmvaltool run --diagnostics=diagnostic1 recipe_python.yml

To get help on additional commands, please use

esmvaltool --help

Note: ESMValTool command line interface is created using the Fire python package. This package supports the creation of completion scripts for the Bash and Fish shells. Go to https://google.github.io/python-fire/using-cli/ #python-fires-flags to learn how to set up them.

OUTPUT

ESMValTool automatically generates a new output directory with every run. The location is determined by the output_dir option in the config-user.yml file, the recipe name, and the date and time, using the the format: YYYYM-MDD_HHMMSS.

For instance, a typical output location would be: output_directory/recipe_ocean_amoc_20190118_1027/

This is effectively produced by the combination: output_dir/recipe_name_YYYYMMDD_HHMMSS/

This directory will contain 4 further subdirectories:

- 1. *Diagnostic output* (work): A place for any diagnostic script results that are not plots, e.g. files in NetCDF format (depends on the diagnostics).
- 2. Plots: The location for all the plots, split by individual diagnostics and fields.
- 3. *Run*: This directory includes all log files, a copy of the recipe, a summary of the resource usage, and the *settings.yml* interface files and temporary files created by the diagnostic scripts.
- 4. *Preprocessed datasets* (preproc): This directory contains all the preprocessed netcdfs data and the *metadata.yml* interface files. Note that by default this directory will be deleted after each run, because most users will only need the results from the diagnostic scripts.

6.1 Preprocessed datasets

The preprocessed datasets will be stored to the preproc/ directory. Each variable in each diagnostic will have its own the *metadata.yml* interface files saved in the preproc directory.

If the option save_intermediary_cubes is set to true in the config-user.yml file, then the intermediary cubes will also be saved here. This option is set to false in the default config-user.yml file.

If the option remove_preproc_dir is set to true in the config-user.yml file, then the preproc directory will be deleted after the run completes. This option is set to true in the default config-user.yml file.

6.2 Run

The log files in the run directory are automatically generated by ESMValTool and create a record of the output messages produced by ESMValTool and they are saved in the run directory. They can be helpful for debugging or monitoring the job, but also allow a record of the job output to screen after the job has been completed.

The run directory will also contain a copy of the recipe and the *settings.yml* file, described below. The run directory is also where the diagnostics are executed, and may also contain several temporary files while diagnostics are running.

6.3 Diagnostic output

The work/ directory will contain all files that are output at the diagnostic stage. Ie, the model data is preprocessed by ESMValTool and stored in the preproc/ directory. These files are opened by the diagnostic script, then some processing is applied. Once the diagnostic level processing has been applied, the results should be saved to the work directory.

6.4 Plots

The plots directory is where diagnostics save their output figures. These plots are saved in the format requested by the option *output_file_type* in the config-user.yml file.

6.5 Settings.yml

The settings.yml file is automatically generated by ESMValTool. Each diagnostic will produce a unique settings.yml file.

The settings.yml file passes several global level keys to diagnostic scripts. This includes several flags from the configuser.yml file (such as 'write_netcdf', 'write_plots', etc...), several paths which are specific to the diagnostic being run (such as 'plot_dir' and 'run_dir') and the location on disk of the metadata.yml file (described below).

```
input_files:[[...]recipe_ocean_bgc_20190118_134855/preproc/diag_timeseries_scalars/
→mfo/metadata.yml]
log_level: debug
output_file_type: png
plot_dir: [...]recipe_ocean_bgc_20190118_134855/plots/diag_timeseries_scalars/Scalar_
-→timeseries
profile_diagnostic: false
recipe: recipe_ocean_bqc.yml
run_dir: [...]recipe_ocean_bqc_20190118_134855/run/diag_timeseries_scalars/Scalar_
→timeseries
script: Scalar_timeseries
version: 2.0al
work_dir: [...]recipe_ocean_bgc_20190118_134855/work/diag_timeseries_scalars/Scalar_
⇔timeseries
write netcdf: true
write plots: true
```

The first item in the settings file will be a list of *Metadata.yml* files. There is a metadata.yml file generated for each field in each diagnostic.

6.6 Metadata.yml

The metadata.yml files is automatically generated by ESMValTool. Along with the settings.yml file, it passes all the paths, boolean flags, and additional arguments that your diagnostic needs to know in order to run.

The metadata is loaded from cfg as a dictionairy object in python diagnostics.

Here is an example metadata.yml file:

```
?
 [...]/recipe_ocean_bgc_20190118_134855/preproc/diag_timeseries_scalars/mfo/CMIP5_
↔HadGEM2-ES_Omon_historical_r1i1p1_TOOM_mfo_2002-2004.nc
 : cmor_table: CMIP5
 dataset: HadGEM2-ES
 diagnostic: diag_timeseries_scalars
 end_year: 2004
 ensemble: r1i1p1
 exp: historical
 field: TOOM
 filename: [...]recipe_ocean_bgc_20190118_134855/preproc/diag_timeseries_scalars/mfo/
→CMIP5_HadGEM2-ES_Omon_historical_r1i1p1_TO0M_mfo_2002-2004.nc
 frequency: mon
 institute: [INPE, MOHC]
 long_name: Sea Water Transport
 mip: Omon
 modeling_realm: [ocean]
 preprocessor: prep_timeseries_scalar
 project: CMIP5
 recipe_dataset_index: 0
 short_name: mfo
 standard_name: sea_water_transport_across_line
 start_year: 2002
 units: kg s-1
 variable_group: mfo
```

As you can see, this is effectively a dictionary with several items including data paths, metadata and other information.

There are several tools available in python which are built to read and parse these files. The tools are available in the shared directory in the diagnostics directory.

Part II

The recipe format

SEVEN

OVERVIEW

After config-user.yml, the recipe.yml is the second file the user needs to pass to esmvaltool as command line option, at each run time point. Recipes contain the data and data analysis information and instructions needed to run the diagnostic(s), as well as specific diagnostic-related instructions.

Broadly, recipes contain a general section summarizing the provenance and functionality of the diagnostics, the datasets which need to be run, the preprocessors that need to be applied, and the diagnostics which need to be run over the preprocessed data. This information is provided to ESMValTool in four main recipe sections: *Documentation, Datasets, Preprocessors* and *Diagnostics*, respectively.

7.1 Recipe section: documentation

The documentation section includes:

- The recipe's author's user name (authors, matching the definitions in the References configuration file)
- A description of the recipe (description, written in MarkDown format)
- A list of scientific references (references, matching the definitions in the *References configuration file*)
- the project or projects associated with the recipe (projects, matching the definitions in the *References con-figuration file*)

For example, the documentation section of recipes/recipe_ocean_amoc.yml is the following:

```
documentation:
  description: |
    Recipe to produce time series figures of the derived variable, the
    Atlantic meridional overturning circulation (AMOC).
    This recipe also produces transect figures of the stream functions for
    the years 2001-2004.
authors:
    - demo_le
maintainer:
    - demo_le
references:
    - demora2018gmd
projects:
    - ukesm
```

Note: Note that all authors, projects, and references mentioned in the description section of the recipe need to be included in the config-references.yml file. The author name uses the format: surname_name. For instance, John Doe would be: doe_john. This information can be omitted by new users whose name is not yet included in config-references.yml.

7.2 Recipe section: datasets

The datasets section includes dictionaries that, via key-value pairs, define standardized data specifications:

- dataset name (key dataset, value e.g. MPI-ESM-LR or UKESM1-0-LL)
- project (key project, value CMIP5 or CMIP6 for CMIP data, OBS for observational data, ana4mips for ana4mips data, obs4mips for obs4mips data, EMAC for EMAC data)
- experiment (key exp, value e.g. historical, amip, piControl, RCP8.5)
- mip (for CMIP data, key mip, value e.g. Amon, Omon, LImon)
- ensemble member (key ensemble, value e.g. r1i1p1, r1i1p1f1)
- time range (e.g. key-value start_year: 1982, end_year: 1990. Please note that yaml interprets numbers with a leading 0 as octal numbers, so we recommend to avoid them. For example, use 128 to specify the year 128 instead of 0128.)
- model grid (native grid grid: gn or regridded grid grid: gr, for CMIP6 data only).

For example, a datasets section could be:

```
datasets:
  - {dataset: CanESM2, project: CMIP5, exp: historical, ensemble: rlilp1, start_year:_
  - {dataset: UKESM1-0-LL, project: CMIP6, exp: historical, ensemble: rlilp1f2, start_
  - {dataset: UKESM1-0-LL, project: CMIP6, exp: historical, ensemble: rlilp1f2, start_
  - {dataset: EC-EARTH3, alias: custom_alias, project: CMIP6, exp: historical, _
  - ensemble: rlilp1f1, start_year: 2001, end_year: 2004, grid: gn}
```

It is possible to define the experiment as a list to concatenate two experiments. Here it is an example concatenating the *historical* experiment with *rcp85*

```
datasets:
  - {dataset: CanESM2, project: CMIP5, exp: [historical, rcp85], ensemble: r1i1p1,_
  -start_year: 2001, end_year: 2004}
```

It is also possible to define the ensemble as a list when the two experiments have different ensemble names. In this case, the specified datasets are concatenated into a single cube:

ESMValTool also supports a simplified syntax to add multiple ensemble members from the same dataset. In the ensemble key, any element in the form (x:y) will be replaced with all numbers from x to y (both inclusive), adding a dataset entry for each replacement. For example, to add ensemble members r1i1p1 to r10i1p1 you can use the following abbreviated syntax:

It can be included multiple times in one definition. For example, to generate the datasets definitions for the ensemble members rli1p1 to r5i1p1 and from rli2p1 to r5i1p1 you can use:

```
datasets:
  - {dataset: CanESM2, project: CMIP5, exp: historical, ensemble: "r(1:5)i(1:2)p1",
  -start_year: 2001, end_year: 2004}
```

Please, bear in mind that this syntax can only be used in the ensemble tag. Also, note that the combination of multiple experiments and ensembles, like exp: [historical, rcp85], ensemble: [r1i1p1, "r(2:3)i1p1"] is not supported and will raise an error.

Note that this section is not required, as datasets can also be provided in the *Diagnostics* section.

7.3 Recipe section: preprocessors

The preprocessor section of the recipe includes one or more preprocessors, each of which may call the execution of one or several preprocessor functions.

Each preprocessor section includes:

- A preprocessor name (any name, under preprocessors);
- A list of preprocessor steps to be executed (choose from the API);
- Any or none arguments given to the preprocessor steps;
- The order that the preprocessor steps are applied can also be specified using the custom_order preprocessor function.

The following snippet is an example of a preprocessor named prep_map that contains multiple preprocessing steps (*Horizontal regridding* with two arguments, *Time manipulation* with no arguments (i.e., calculating the average over the time dimension) and *Multi-model statistics* with two arguments):

```
preprocessors:
    prep_map:
    regrid:
        target_grid: 1x1
        scheme: linear
        climate_statistics:
        operator: mean
        multi_model_statistics:
        span: overlap
        statistics: [mean]
```

Note: In this case no preprocessors section is needed the workflow will apply a default preprocessor consisting of only basic operations like: loading data, applying CMOR checks and fixes (*CMORization and dataset-specific fixes*) and saving the data to disk.

Preprocessor operations will be applied using the default order as listed in *Preprocessor functions*. Preprocessor tasks can be set to run in the order they are listed in the recipe by adding custom_order: true to the preprocessor definition.

7.4 Recipe section: diagnostics

The diagnostics section includes one or more diagnostics. Each diagnostic section will include:

- the variable(s) to preprocess, including the preprocessor to be applied to each variable;
- the diagnostic script(s) to be run;
- a description of the diagnostic and lists of themes and realms that it applies to;
- an optional additional_datasets section.

7.4.1 The diagnostics section defines tasks

The diagnostic section(s) define the tasks that will be executed when running the recipe. For each variable a preprocessing task will be defined and for each diagnostic script a diagnostic task will be defined. If variables need to be derived from other variables, a preprocessing task for each of the variables needed to derive that variable will be defined as well. These tasks can be viewed in the main_log_debug.txt file that is produced every run. Each task has a unique name that defines the subdirectory where the results of that task are stored. Task names start with the name of the diagnostic section followed by a '/' and then the name of the variable section for a preprocessing task or the name of the diagnostic script section for a diagnostic task.

A (simplified) example diagnostics section could look like

```
diagnostics:
    diagnostic_name:
    description: Air temperature tutorial diagnostic.
    themes:
        - phys
    realms:
        - atmos
    variables:
        variable_name:
        short_name: ta
        preprocessor: preprocessor_name
        mip: Amon
    scripts:
        script_name:
        script_name:
        script: examples/diagnostic.py
```

Note that the example recipe above contains a single diagnostic section called diagnostic_name and will result in two tasks:

- a preprocessing task called diagnostic_name/variable_name that will preprocess air temperature data for each dataset in the *Datasets* section of the recipe (not shown).
- a diagnostic task called diagnostic_name/script_name

The path to the script provided in the script option should be either the absolute path to the script, or the path relative to the esmvaltool/diag_scripts directory.

Depending on the installation configuration, you may get an error of "file does not exist" when the system tries to run the diagnostic script using relative paths. If this happens, use an absolute path instead.

7.4.2 Ancestor tasks

Some tasks require the result of other tasks to be ready before they can start, e.g. a diagnostic script needs the preprocessed variable data to start. Thus each tasks has zero or more ancestor tasks. By default, each diagnostic task in a diagnostic section has all variable preprocessing tasks in that same section as ancestors. However, this can be changed using the ancestors keyword. Note that wildcard expansion can be used to define ancestors.

```
diagnostics:
 diagnostic_1:
   variables:
      airtemp:
        short_name: ta
        preprocessor: preprocessor_name
        mip: Amon
    scripts:
      script_a:
        script: diagnostic_a.py
 diagnostic_2:
    variables:
      precip:
        short_name: pr
        preprocessor: preprocessor_name
        mip: Amon
    scripts:
      script_b:
        script: diagnostic_b.py
        ancestors: [diagnostic_1/script_a, precip]
```

The example recipe above will result in four tasks:

- a preprocessing task called diagnostic_1/airtemp
- a diagnostic task called diagnostic_1/script_a
- a preprocessing task called diagnostic_2/precip
- a diagnostic task called diagnostic_2/script_b

the preprocessing tasks do not have any ancestors, while the diagnostic_a.py script will receive the preprocessed air temperature data (has ancestor diagnostic_1/airtemp) and the diagnostic_b.py script will receive the results of diagnostic_a.py and the preprocessed precipitation data (has ancestors diagnostic_1/script_a and diagnostic_2/precip).

7.4.3 Task priority

Tasks are assigned a priority, with tasks appearing earlier on in the recipe getting higher priority. The tasks will be executed sequentially or in parellel, depending on the setting of max_parallel_tasks in the *User configuration file*. When there are fewer than max_parallel_tasks running, tasks will be started according to their priority. For obvious reasons, only tasks that are not waiting for ancestor tasks can be started. This feature makes it possible to reduce the processing time of recipes with many tasks, by placing tasks that take relatively long near the top of the recipe. Of course this only works when settings max_parallel_tasks to a value larger than 1. The current priority and run time of individual tasks can be seen in the log messages shown when running the tool (a lower number means higher priority).

7.4.4 Variable and dataset definitions

To define a variable/dataset combination that corresponds to an actual variable from a dataset, the keys in each variable section are combined with the keys of each dataset definition. If two versions of the same key are provided, then the key in the datasets section will take precedence over the keys in variables section. For many recipes it makes more sense to define the start_year and end_year items in the variable section, because the diagnostic script assumes that all the data has the same time range.

Variable short names usually do not change between datasets supported by ESMValCore, as they are usually changed to match CMIP. Nevertheless, there are small changes in variable names in CMIP6 with respect to CMIP5 (i.e. sea ice concentration changed from sic to siconc). ESMValCore is aware of some of them and can do the automatic translation when needed. It will even do the translation in the preprocessed file so the diagnostic does not have to deal with this complexity, setting the short name in all files to match the one used by the recipe. For example, if sic is requested, ESMValTool will find sic or siconc depending on the project, but all preprocessed files while use sic as their short_name. If the recipe requested siconc, the preprocessed files will be identical except that they will use the short_name siconc instead.

7.4.5 Diagnostic and variable specific datasets

The additional_datasets option can be used to add datasets beyond those listed in the *Datasets* section. This is useful if specific datasets need to be used only by a specific diagnostic or variable, i.e. it can be added both at diagnostic level, where it will apply to all variables in that diagnostic section or at individual variable level. For example, this can be a good way to add observational datasets, which are usually variable-specific.

7.4.6 Running a simple diagnostic

The following example, taken from recipe_ocean_example.yml, shows a diagnostic named *diag_map*, which loads the temperature at the ocean surface between the years 2001 and 2003 and then passes it to the prep_map pre-processor. The result of this process is then passed to the ocean diagnostic map script, ocean/diagnostic_maps.py.

```
diagnostics:
diag_map:
  description: Global Ocean Surface regridded temperature map
  variables:
    tos: # Temperature at the ocean surface
        preprocessor: prep_map
        start_year: 2001
        end_year: 2003
    scripts:
    Global_Ocean_Surface_regrid_map:
        script: ocean/diagnostic_maps.py
```

7.4.7 Passing arguments to a diagnostic script

The diagnostic script section(s) may include custom arguments that can be used by the diagnostic script; these arguments are stored at runtime in a dictionary that is then made available to the diagnostic script via the interface link, independent of the language the diagnostic script is written in. Here is an example of such groups of arguments:

```
scripts:
autoassess_strato_test_1: &autoassess_strato_test_1_settings
script: autoassess/autoassess_area_base.py
title: "Autoassess Stratosphere Diagnostic Metric MPI-MPI"
area: stratosphere
control_model: MPI-ESM-LR
exp_model: MPI-ESM-LR
obs_models: [ERA-Interim] # list to hold models that are NOT for metrics but for_
$\circ$obs operations
additional_metrics: [ERA-Interim, inmcm4] # list to hold additional datasets for_
$\circ$metrics
```

In this example, apart from specifying the diagnostic script script: autoassess/ autoassess_area_base.py, we pass a suite of parameters to be used by the script (area, control_model etc). These parameters are stored in key-value pairs in the diagnostic configuration file, an interface file that can be used by importing the run_diagnostic utility:

```
from esmvaltool.diag_scripts.shared import run_diagnostic
# write the diagnostic code here e.g.
def run some diagnostic (my_area, my_control_model, my_exp_model):
    """Diagnostic to be run."""
   if my_area == 'stratosphere':
       diag = my_control_model / my_exp_model
        return diag
def main(cfg):
    """Main diagnostic run function."""
   my_area = cfg['area']
   my_control_model = cfg['control_model']
   my_exp_model = cfg['exp_model']
   run_some_diagnostic(my_area, my_control_model, my_exp_model)
if __name__ == '__main__':
   with run_diagnostic() as config:
       main(config)
```

This way a lot of the optional arguments necessary to a diagnostic are at the user's control via the recipe.

7.4.8 Running your own diagnostic

If the user wants to test a newly-developed my_first_diagnostic.py which is not yet part of the ESMValTool diagnostics library, he/she do it by passing the absolute path to the diagnostic:

```
diagnostics:
    myFirstDiag:
        description: John Doe wrote a funny diagnostic
        variables:
```

(continues on next page)

(continued from previous page)

```
tos: # Temperature at the ocean surface
    preprocessor: prep_map
    start_year: 2001
    end_year: 2003
scripts:
    JoeDiagFunny:
    script: /home/users/john_doe/esmvaltool_testing/my_first_diagnostic.py
```

This way the user may test a new diagnostic thoroughly before committing to the GitHub repository and including it in the ESMValTool diagnostics library.

7.4.9 Re-using parameters from one script to another

Due to yaml features it is possible to recycle entire diagnostics sections for use with other diagnostics. Here is an example:

```
scripts:
  cycle: &cycle_settings
    script: perfmetrics/main.ncl
    plot_type: cycle
    time_avg: monthlyclim
  grading: &grading_settings
    <<: *cycle_settings
    plot_type: cycle_latlon
    calc_grading: true
    normalization: [centered_median, none]
```

In this example the hook &cycle_settings can be used to pass the cycle: parameters to grading: via the shortcut <<: *cycle_settings.

CHAPTER

EIGHT

PREPROCESSOR

In this section, each of the preprocessor modules is described, roughly following the default order in which preprocessor functions are applied:

- Variable derivation
- CMORization and dataset-specific fixes
- Vertical interpolation
- Weighting
- Land-sea masking
- Horizontal regridding
- Missing values masks
- Multi-model statistics
- Time manipulation
- Area manipulation
- Volume manipulation
- Cycles
- Detrend
- Unit conversion
- Other

See Preprocessor functions for implementation details and the exact default order.

8.1 Overview

The ESMValTool preprocessor can be used to perform a broad range of operations on the input data before diagnostics or metrics are applied. The preprocessor performs these operations in a centralized, documented and efficient way, thus reducing the data processing load on the diagnostics side. For an overview of the preprocessor structure see the *Recipe section: preprocessors*.

Each of the preprocessor operations is written in a dedicated python module and all of them receive and return an Iris cube, working sequentially on the data with no interactions between them. The order in which the preprocessor operations is applied is set by default to minimize the loss of information due to, for example, temporal and spatial subsetting or multi-model averaging. Nevertheless, the user is free to change such order to address specific scientific requirements, but keeping in mind that some operations must be necessarily performed in a specific order. This is the

case, for instance, for multi-model statistics, which required the model to be on a common grid and therefore has to be called after the regridding module.

8.2 Variable derivation

The variable derivation module allows to derive variables which are not in the CMIP standard data request using standard variables as input. The typical use case of this operation is the evaluation of a variable which is only available in an observational dataset but not in the models. In this case a derivation function is provided by the ESMValTool in order to calculate the variable and perform the comparison. For example, several observational datasets deliver total column ozone as observed variable (*toz*), but CMIP models only provide the ozone 3D field. In this case, a derivation function is provided to vertically integrate the ozone and obtain total column ozone for direct comparison with the observations.

To contribute a new derived variable, it is also necessary to define a name for it and to provide the corresponding CMOR table. This is to guarantee the proper metadata definition is attached to the derived data. Such custom CMOR tables are collected as part of the ESMValCore package. By default, the variable derivation will be applied only if the variable is not already available in the input data, but the derivation can be forced by setting the appropriate flag.

```
variables:
    toz:
        derive: true
        force_derivation: false
```

The required arguments for this module are two boolean switches:

- derive: activate variable derivation
- force_derivation: force variable derivation even if the variable is directly available in the input data.

See also *esmvalcore.preprocessor.derive()*. To get an overview on derivation scripts and how to implement new ones, please go to *Variable derivation*.

8.3 CMORization and dataset-specific fixes

8.3.1 Data checking

Data preprocessed by ESMValTool is automatically checked against its cmor definition. To reduce the impact of this check while maintaining it as reliable as possible, it is split in two parts: one will check the metadata and will be done just after loading and concatenating the data and the other one will check the data itself and will be applied after all extracting operations are applied to reduce the amount of data to process.

Checks include, but are not limited to:

- Requested coordinates are present and comply with their definition.
- · Correctness of variable names, units and other metadata.
- · Compliance with the valid minimum and maximum values allowed if defined.

The most relevant (i.e. a missing coordinate) will raise an error while others (i.e an incorrect long name) will be reported as a warning.

Some of those issues will be fixed automatically by the tool, including the following:

- Incorrect standard or long names.
- Incorrect units, if they can be converted to the correct ones.

- Direction of coordinates.
- Automatic clipping of longitude to 0 360 interval.

8.3.2 Dataset specific fixes

Sometimes, the checker will detect errors that it can not fix by itself. ESMValTool deals with those issues by applying specific fixes for those datasets that require them. Fixes are applied at three different preprocessor steps:

- fix_file: apply fixes directly to a copy of the file. Copying the files is costly, so only errors that prevent Iris to load the file are fixed here. See *esmvalcore.preprocessor.fix_file()*
- fix_metadata: metadata fixes are done just before concatenating the cubes loaded from different files in the final one. Automatic metadata fixes are also applied at this step. See *esmvalcore.preprocessor*. *fix_metadata()*
- fix_data: data fixes are applied before starting any operation that will alter the data itself. Automatic data fixes are also applied at this step. See *esmvalcore.preprocessor.fix_data()*

To get an overview on data fixes and how to implement new ones, please go to Dataset fixes.

8.4 Vertical interpolation

Vertical level selection is an important aspect of data preprocessing since it allows the scientist to perform a number of metrics specific to certain levels (whether it be air pressure or depth, e.g. the Quasi-Biennial-Oscillation (QBO) u30 is computed at 30 hPa). Dataset native vertical grids may not come with the desired set of levels, so an interpolation operation will be needed to regrid the data vertically. ESMValTool can perform this vertical interpolation via the extract_levels preprocessor. Level extraction may be done in a number of ways.

Level extraction can be done at specific values passed to extract_levels as levels: with its value a list of levels (note that the units are CMOR-standard, Pascals (Pa)):

```
preprocessors:
    preproc_select_levels_from_list:
        extract_levels:
        levels: [100000., 50000., 3000., 1000.]
        scheme: linear
```

It is also possible to extract the CMIP-specific, CMOR levels as they appear in the CMOR table, e.g. plev10 or plev17 or plev19 etc:

```
preprocessors:
    preproc_select_levels_from_cmip_table:
        extract_levels:
        levels: {cmor_table: CMIP6, coordinate: plev10}
        scheme: nearest
```

Of good use is also the level extraction with values specific to a certain dataset, without the user actually polling the dataset of interest to find out the specific levels: e.g. in the example below we offer two alternatives to extract the levels and vertically regrid onto the vertical levels of ERA-Interim:

```
preprocessors:
    preproc_select_levels_from_dataset:
        extract_levels:
        levels: ERA-Interim
```

(continues on next page)

(continued from previous page)

```
# This also works, but allows specifying the pressure coordinate name
# levels: {dataset: ERA-Interim, coordinate: air_pressure}
scheme: linear_horizontal_extrapolate_vertical
```

By default, vertical interpolation is performed in the dimension coordinate of the z axis. If you want to explicitly declare the z axis coordinate to use (for example, air_pressure' in variables that are provided in model levels and not pressure levels) you can override that automatic choice by providing the name of the desired coordinate:

```
preprocessors:
    preproc_select_levels_from_dataset:
        extract_levels:
        levels: ERA-Interim
        scheme: linear_horizontal_extrapolate_vertical
        coordinate: air_pressure
```

- See also esmvalcore.preprocessor.extract_levels().
- See also esmvalcore.preprocessor.get_cmor_levels().

Note: For both vertical and horizontal regridding one can control the extrapolation mode when defining the interpolation scheme. Controlling the extrapolation mode allows us to avoid situations where extrapolating values makes little physical sense (e.g. extrapolating beyond the last data point). The extrapolation mode is controlled by the *extrapolation_mode* keyword. For the available interpolation schemes available in Iris, the extrapolation_mode keyword must be one of:

- extrapolate: the extrapolation points will be calculated by extending the gradient of the closest two points;
- error: a ValueError exception will be raised, notifying an attempt to extrapolate;
- nan: the extrapolation points will be be set to NaN;
- mask: the extrapolation points will always be masked, even if the source data is not a MaskedArray; or
- nanmask: if the source data is a MaskedArray the extrapolation points will be masked, otherwise they will be set to NaN.

8.5 Weighting

8.5.1 Land/sea fraction weighting

This preprocessor allows weighting of data by land or sea fractions. In other words, this function multiplies the given input field by a fraction in the range 0-1 to account for the fact that not all grid points are completely land- or sea-covered.

The application of this preprocessor is very important for most carbon cycle variables (and other land surface outputs), which are e.g. reported in units of $kgC m^{-2}$. Here, the surface unit actually refers to 'square meter of land/sea' and NOT 'square meter of gridbox'. In order to integrate these globally or regionally one has to weight by both the surface quantity and the land/sea fraction.

For example, to weight an input field with the land fraction, the following preprocessor can be used:

```
preprocessors:
    preproc_weighting:
        weighting_landsea_fraction:
```

(continues on next page)

(continued from previous page)

```
area_type: land
exclude: ['CanESM2', 'reference_dataset']
```

Allowed arguments for the keyword area_type are land (fraction is 1 for grid cells with only land surface, 0 for grid cells with only sea surface and values in between 0 and 1 for coastal regions) and sea (1 for sea, 0 for land, in between for coastal regions). The optional argument exclude allows to exclude specific datasets from this preprocessor, which is for example useful for climate models which do not offer land/sea fraction files. This arguments also accepts the special dataset specifiers reference_dataset and alternative_dataset.

Optionally you can specify your own custom fx variable to be used in cases when e.g. a certain experiment is preferred for fx data retrieval:

See also esmvalcore.preprocessor.weighting_landsea_fraction().

8.6 Masking

8.6.1 Introduction to masking

Certain metrics and diagnostics need to be computed and performed on specific domains on the globe. The ESMVal-Tool preprocessor supports filtering the input data on continents, oceans/seas and ice. This is achieved by masking the model data and keeping only the values associated with grid points that correspond to, e.g., land, ocean or ice surfaces, as specified by the user. Where possible, the masking is realized using the standard mask files provided together with the model data as part of the CMIP data request (the so-called fx variable). In the absence of these files, the Natural Earth masks are used: although these are not model-specific, they represent a good approximation since they have a much higher resolution than most of the models and they are regularly updated with changing geographical features.

8.6.2 Land-sea masking

In ESMValTool, land-sea-ice masking can be done in two places: in the preprocessor, to apply a mask on the data before any subsequent preprocessing step and before running the diagnostic, or in the diagnostic scripts themselves. We present both these implementations below.

To mask out a certain domain (e.g., sea) in the preprocessor, mask_landsea can be used:

```
preprocessors:
    preproc_mask:
    mask_landsea:
    mask_out: sea
```

and requires only one argument: mask_out: either land or sea.

The preprocessor automatically retrieves the corresponding mask (fx: stfof in this case) and applies it so that sea-covered grid cells are set to missing. Conversely, it retrieves the fx: sftlf mask when land needs to be masked out, respectively.

Optionally you can specify your own custom fx variable to be used in cases when e.g. a certain experiment is preferred for fx data retrieval:

```
preprocessors:
landmask:
    mask_landsea:
    mask_out: sea
    fx_variables: [{'short_name': 'sftlf', 'exp': 'piControl'}, {'short_name':
    →'sftof', 'exp': 'piControl'}]
```

If the corresponding fx file is not found (which is the case for some models and almost all observational datasets), the preprocessor attempts to mask the data using Natural Earth mask files (that are vectorized rasters). As mentioned above, the spatial resolution of the the Natural Earth masks are much higher than any typical global model (10m for land and glaciated areas and 50m for ocean masks).

See also esmvalcore.preprocessor.mask_landsea().

8.6.3 Ice masking

Note that for masking out ice sheets, the preprocessor uses a different function, to ensure that both land and sea or ice can be masked out without losing generality. To mask ice out, mask_landseaice can be used:

```
preprocessors:
    preproc_mask:
    mask_landseaice:
    mask_out: ice
```

and requires only one argument: mask_out: either landsea or ice.

As in the case of mask_landsea, the preprocessor automatically retrieves the fx_variables: [sftgif] mask.

Optionally you can specify your own custom fx variable to be used in cases when e.g. a certain experiment is preferred for fx data retrieval:

```
preprocessors:
landseaicemask:
    mask_landseaice:
    mask_out: sea
    fx_variables: [{'short_name': 'sftgif', 'exp': 'piControl'}]
```

See also esmvalcore.preprocessor.mask_landseaice().

8.6.4 Glaciated masking

For masking out glaciated areas a Natural Earth shapefile is used. To mask glaciated areas out, mask_glaciated can be used:

```
preprocessors:
    preproc_mask:
        mask_glaciated:
        mask_out: glaciated
```

and it requires only one argument: mask_out: only glaciated.

```
See also esmvalcore.preprocessor.mask_landseaice().
```

8.6.5 Missing values masks

Missing (masked) values can be a nuisance especially when dealing with multimodel ensembles and having to compute multimodel statistics; different numbers of missing data from dataset to dataset may introduce biases and artificially assign more weight to the datasets that have less missing data. This is handled in ESMValTool via the missing values masks: two types of such masks are available, one for the multimodel case and another for the single model case.

The multimodel missing values mask (mask_fillvalues) is a preprocessor step that usually comes after all the single-model steps (regridding, area selection etc) have been performed; in a nutshell, it combines missing values masks from individual models into a multimodel missing values mask; the individual model masks are built according to common criteria: the user chooses a time window in which missing data points are counted, and if the number of missing data points relative to the number of total data points in a window is less than a chosen fractional threshold, the window is discarded i.e. all the points in the window are masked (set to missing).

```
preprocessors:
    missing_values_preprocessor:
    mask_fillvalues:
        threshold_fraction: 0.95
        min_value: 19.0
        time_window: 10.0
```

In the example above, the fractional threshold for missing data vs. total data is set to 95% and the time window is set to 10.0 (units of the time coordinate units). Optionally, a minimum value threshold can be applied, in this case it is set to 19.0 (in units of the variable units).

See also esmvalcore.preprocessor.mask_fillvalues().

8.6.6 Common mask for multiple models

It is possible to use mask_fillvalues to create a combined multimodel mask (all the masks from all the analyzed models combined into a single mask); for that purpose setting the threshold_fraction to 0 will not discard any time windows, essentially keeping the original model masks and combining them into a single mask; here is an example:

8.6.7 Minimum, maximum and interval masking

Thresholding on minimum and maximum accepted data values can also be performed: masks are constructed based on the results of thresholding; inside and outside interval thresholding and masking can also be performed. These functions are mask_above_threshold, mask_below_threshold, mask_inside_range, and mask_outside_range.

These functions always take a cube as first argument and either threshold for threshold masking or the pair minimum, ``maximum for interval masking.

See also esmvalcore.preprocessor.mask_above_threshold() and related functions.

8.7 Horizontal regridding

Regridding is necessary when various datasets are available on a variety of *lat-lon* grids and they need to be brought together on a common grid (for various statistical operations e.g. multimodel statistics or for e.g. direct inter-comparison or comparison with observational datasets). Regridding is conceptually a very similar process to interpolation (in fact, the regridder engine uses interpolation and extrapolation, with various schemes). The primary difference is that interpolation is based on sample data points, while regridding is based on the horizontal grid of another cube (the reference grid).

The underlying regridding mechanism in ESMValTool uses the cube.regrid() from Iris.

The use of the horizontal regridding functionality is flexible depending on what type of reference grid and what interpolation scheme is preferred. Below we show a few examples.

8.7.1 Regridding on a reference dataset grid

The example below shows how to regrid on the reference dataset ERA-Interim (observational data, but just as well CMIP, obs4mips, or ana4mips datasets can be used); in this case the *scheme* is *linear*.

```
preprocessors:
    regrid_preprocessor:
    regrid:
        target_grid: ERA-Interim
        scheme: linear
```

8.7.2 Regridding on an MxN grid specification

The example below shows how to regrid on a reference grid with a cell specification of 2.5×2.5 degrees. This is similar to regridding on reference datasets, but in the previous case the reference dataset grid cell specifications are not necessarily known a priori. Regridding on an MxN cell specification is oftentimes used when operating on localized data.

```
preprocessors:
    regrid_preprocessor:
    regrid:
        target_grid: 2.5x2.5
        scheme: nearest
```

In this case the NearestNeighbour interpolation scheme is used (see below for scheme definitions).

When using a MxN type of grid it is possible to offset the grid cell centrepoints using the *lat_offset* and lon_offset arguments:

- lat_offset: offsets the grid centers of the latitude coordinate w.r.t. the pole by half a grid step;
- lon_offset: offsets the grid centers of the longitude coordinate w.r.t. Greenwich meridian by half a grid step.

```
preprocessors:
    regrid_preprocessor:
    regrid:
        target_grid: 2.5x2.5
        lon_offset: True
        lat_offset: True
        scheme: nearest
```

8.7.3 Regridding (interpolation, extrapolation) schemes

The schemes used for the interpolation and extrapolation operations needed by the horizontal regridding functionality directly map to their corresponding implementations in Iris:

- linear: Linear(extrapolation_mode='mask').
- linear_extrapolate: Linear(extrapolation_mode='extrapolate').
- nearest: Nearest(extrapolation_mode='mask').
- area_weighted: AreaWeighted().
- unstructured_nearest: UnstructuredNearest().

See also esmvalcore.preprocessor.regrid()

Note: For both vertical and horizontal regridding one can control the extrapolation mode when defining the interpolation scheme. Controlling the extrapolation mode allows us to avoid situations where extrapolating values makes little physical sense (e.g. extrapolating beyond the last data point). The extrapolation mode is controlled by the *extrapolation_mode* keyword. For the available interpolation schemes available in Iris, the extrapolation_mode keyword must be one of:

- extrapolate the extrapolation points will be calculated by extending the gradient of the closest two points;
- error a ValueError exception will be raised, notifying an attempt to extrapolate;
- nan the extrapolation points will be be set to NaN;
- mask the extrapolation points will always be masked, even if the source data is not a MaskedArray; or
- nanmask if the source data is a MaskedArray the extrapolation points will be masked, otherwise they will be set to NaN.

Note: The regridding mechanism is (at the moment) done with fully realized data in memory, so depending on how fine the target grid is, it may use a rather large amount of memory. Empirically target grids of up to 0.5×0.5 degrees should not produce any memory-related issues, but be advised that for resolutions of < 0.5 degrees the regridding becomes very slow and will use a lot of memory.

8.8 Multi-model statistics

Computing multi-model statistics is an integral part of model analysis and evaluation: individual models display a variety of biases depending on model set-up, initial conditions, forcings and implementation; comparing model data to observational data, these biases have a significantly lower statistical impact when using a multi-model ensemble. ESMValTool has the capability of computing a number of multi-model statistical measures: using the preprocessor module multi_model_statistics will enable the user to ask for either a multi-model mean, median, max, min, std, and / or pXX.YY with a set of argument parameters passed to multi_model_statistics. Percentiles can be specified like p1.5 or p95. The decimal point will be replaced by a dash in the output file.

Note that current multimodel statistics in ESMValTool are local (not global), and are computed along the time axis. As such, can be computed across a common overlap in time (by specifying span: overlap argument) or across the full length in time of each model (by specifying span: full argument).

Restrictive computation is also available by excluding any set of models that the user will not want to include in the statistics (by setting exclude: [excluded models list] argument). The implementation has a few restrictions that apply to the input data: model datasets must have consistent shapes, and from a statistical point of

view, this is needed since weights are not yet implemented; also higher dimensional data is not supported (i.e. anything with dimensionality higher than four: time, vertical axis, two horizontal axes).

```
preprocessors:
    multimodel_preprocessor:
    multi_model_statistics:
        span: overlap
        statistics: [mean, median]
        exclude: [NCEP]
```

see also esmvalcore.preprocessor.multi_model_statistics().

When calling the module inside diagnostic scripts, the input must be given as a list of cubes. The output will be saved in a dictionary where each entry contains the resulting cube with the requested statistic operations.

```
from esmvalcore.preprocessor import multi_model_statistics
statistics = multi_model_statistics([cube1,...,cubeN], 'overlap', ['mean', 'median'])
mean_cube = statistics['mean']
median_cube = statistics['median']
```

Note: Note that the multimodel array operations, albeit performed in per-time/per-horizontal level loops to save memory, could, however, be rather memory-intensive (since they are not performed lazily as yet). The Section on *Information on maximum memory required* details the memory intake for different run scenarios, but as a thumb rule, for the multimodel preprocessor, the expected maximum memory intake could be approximated as the number of datasets multiplied by the average size in memory for one dataset.

8.9 Time manipulation

The _time.py module contains the following preprocessor functions:

- *extract_time*: Extract a time range from a cube.
- *extract_season*: Extract only the times that occur within a specific season.
- *extract_month*: Extract only the times that occur within a specific month.
- *daily_statistics*: Compute statistics for each day
- monthly_statistics: Compute statistics for each month
- seasonal_statistics: Compute statistics for each season
- annual_statistics: Compute statistics for each year
- *decadal_statistics*: Compute statistics for each decade
- climate_statistics: Compute statistics for the full period
- anomalies: Compute (standardized) anomalies
- regrid_time: Aligns the time axis of each dataset to have common time points and calendars.
- *timeseries_filter*: Allows application of a filter to the time-series data.

Statistics functions are applied by default in the order they appear in the list. For example, the following example applied to hourly data will retrieve the minimum values for the full period (by season) of the monthly mean of the daily maximum of any given variable.

```
daily_statistics:
    operator: max
monthly_statistics:
    operator: mean
climate_statistics:
    operator: min
    period: season
```

8.9.1 extract_time

This function subsets a dataset between two points in times. It removes all times in the dataset before the first time and after the last time point. The required arguments are relatively self explanatory:

- start_year
- start_month
- start_day
- end_year
- end_month
- end_day

These start and end points are set using the datasets native calendar. All six arguments should be given as integers - the named month string will not be accepted.

See also esmvalcore.preprocessor.extract_time().

8.9.2 extract_season

Extract only the times that occur within a specific season.

This function only has one argument: season. This is the named season to extract. ie: DJF, MAM, JJA, SON.

Note that this function does not change the time resolution. If your original data is in monthly time resolution, then this function will return three monthly datapoints per year.

If you want the seasonal average, then this function needs to be combined with the seasonal_mean function, below.

See also esmvalcore.preprocessor.extract_season().

8.9.3 extract_month

The function extracts the times that occur within a specific month. This function only has one argument: month. This value should be an integer between 1 and 12 as the named month string will not be accepted.

See also esmvalcore.preprocessor.extract_month().

8.9.4 daily_statistics

This function produces statistics for each day in the dataset.

Parameters:

• operator: operation to apply. Accepted values are 'mean', 'median', 'std_dev', 'min', 'max', 'sum' and 'rms'. Default is 'mean'

See also esmvalcore.preprocessor.daily_statistics().

8.9.5 monthly_statistics

This function produces statistics for each month in the dataset.

Parameters:

• operator: operation to apply. Accepted values are 'mean', 'median', 'std_dev', 'min', 'max', 'sum' and 'rms'. Default is 'mean'

See also esmvalcore.preprocessor.monthly_statistics().

8.9.6 seasonal_statistics

This function produces statistics for each season (DJF, MAM, JJA, SON) in the dataset. Note that this function will not check for missing time points. For instance, if you are looking at the DJF field, but your datasets starts on January 1st, the first DJF field will only contain data from January and February.

We recommend using the extract_time to start the dataset from the following December and remove such biased initial datapoints.

Parameters:

• operator: operation to apply. Accepted values are 'mean', 'median', 'std_dev', 'min', 'max', 'sum' and 'rms'. Default is 'mean'

See also esmvalcore.preprocessor.seasonal_mean().

8.9.7 annual_statistics

This function produces statistics for each year.

Parameters:

• operator: operation to apply. Accepted values are 'mean', 'median', 'std_dev', 'min', 'max', 'sum' and 'rms'. Default is 'mean'

See also esmvalcore.preprocessor.annual_statistics().

8.9.8 decadal_statistics

This function produces statistics for each decade.

Parameters:

• operator: operation to apply. Accepted values are 'mean', 'median', 'std_dev', 'min', 'max', 'sum' and 'rms'. Default is 'mean'

See also esmvalcore.preprocessor.decadal_statistics().

8.9.9 climate_statistics

This function produces statistics for the whole dataset. It can produce scalars (if the full period is chosen) or daily, monthly or seasonal statics.

Parameters:

- operator: operation to apply. Accepted values are 'mean', 'median', 'std_dev', 'min', 'max', 'sum' and 'rms'. Default is 'mean'
- period: define the granularity of the statistics: get values for the full period, for each month or day of year. Available periods: 'full', 'season', 'seasonal', 'monthly', 'month', 'mon', 'daily', 'day'. Default is 'full'

Examples:

• Monthly climatology:

```
climate_statistics:
    operator: mean
    period: month
```

• Daily maximum for the full period:

```
climate_statistics:
    operator: max
    period: day
```

• Minimum value in the period:

```
climate_statistics:
    operator: min
    period: full
```

See also esmvalcore.preprocessor.climate_statistics().

8.9.10 anomalies

This function computes the anomalies for the whole dataset. It can compute anomalies from the full, seasonal, monthly and daily climatologies. Optionally standardized anomalies can be calculated.

Parameters:

- period: define the granularity of the climatology to use: full period, seasonal, monthly or daily. Available periods: 'full', 'season', 'seasonal', 'monthly', 'month', 'mon', 'daily', 'day'. Default is 'full'
- reference: Time slice to use as the reference to compute the climatology on. Can be 'null' to use the full cube or a dictionary with the parameters from *extract_time*. Default is null
- standardize: if true calculate standardized anomalies (default: false)

Examples:

• Anomalies from the full period climatology:

anomalies:

• Anomalies from the full period monthly climatology:

```
anomalies:
period: month
```

• Standardized anomalies from the full period climatology:

```
anomalies:
    standardized: true
```

• Standardized Anomalies from the 1979-2000 monthly climatology:

```
anomalies:
    period: month
    reference:
        start_year: 1979
        start_month: 1
        start_day: 1
        end_year: 2000
        end_month: 12
        end_day: 31
        standardize: true
```

See also esmvalcore.preprocessor.anomalies().

8.9.11 regrid_time

This function aligns the time points of each component dataset so that the Iris cubes from different datasets can be subtracted. The operation makes the datasets time points common; it also resets the time bounds and auxiliary coordinates to reflect the artificially shifted time points. Current implementation for monthly and daily data; the frequency is set automatically from the variable CMOR table unless a custom frequency is set manually by the user in recipe.

See also esmvalcore.preprocessor.regrid_time().

8.9.12 timeseries_filter

This function allows the user to apply a filter to the timeseries data. This filter may be of the user's choice (currently only the low-pass Lanczos filter is implemented); the implementation is inspired by this iris example and uses aggregation via a rolling window.

Parameters:

- window: the length of the filter window (in units of cube time coordinate).
- span: period (number of months/days, depending on data frequency) on which weights should be computed e.g. for 2-yearly: span = 24 (2 x 12 months). Make sure span has the same units as the data cube time coordinate.
- filter_type: the type of filter to be applied; default 'lowpass'. Available types: 'lowpass'.

• filter_stats: the type of statistic to aggregate on the rolling window; default 'sum'. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'.

Examples:

• Lowpass filter with a monthly mean as operator:

```
timeseries_filter:
  window: 3 # 3-monthly filter window
  span: 12 # weights computed on the first year
  filter_type: lowpass # low-pass filter
  filter_stats: mean # 3-monthly mean lowpass filter
```

See also esmvalcore.preprocessor.timeseries_filter().

8.10 Area manipulation

The area manipulation module contains the following preprocessor functions:

- *extract_region*: Extract a region from a cube based on lat/lon corners.
- extract_named_regions: Extract a specific region from in the region coordinate.
- *extract_shape*: Extract a region defined by a shapefile.
- *extract_point*: Extract a single point (with interpolation)
- zonal_statistics: Compute zonal statistics.
- meridional_statistics: Compute meridional statistics.
- area_statistics: Compute area statistics.

8.10.1 extract_region

This function masks data outside a rectangular region requested. The boundaries of the region are provided as latitude and longitude coordinates in the arguments:

- start_longitude
- end_longitude
- start_latitude
- end_latitude

Note that this function can only be used to extract a rectangular region. Use <code>extract_shape</code> to extract any other shaped region from a shapefile.

See also esmvalcore.preprocessor.extract_region().

8.10.2 extract_named_regions

This function extracts a specific named region from the data. This function takes the following argument: regions which is either a string or a list of strings of named regions. Note that the dataset must have a region coordinate which includes a list of strings as values. This function then matches the named regions against the requested string.

See also esmvalcore.preprocessor.extract_named_regions().

8.10.3 extract_shape

Extract a shape or a representative point for this shape from the data.

Parameters:

- shapefile: path to the shapefile containing the geometry of the region to be extracted. If the file contains multiple shapes behaviour depends on the decomposed parameter. This path can be relative to auxiliary_data_dir defined in the *User configuration file*.
- method: the method to select the region, selecting either all points contained by the shape or a single representative point. Choose either 'contains' or 'representative'. If not a single grid point is contained in the shape, a representative point will be selected.
- **crop:** by default *extract_region* will be used to crop the data to a minimal rectangular region containing the shape. Set to false to only mask data outside the shape. Data on irregular grids will not be cropped.
- decomposed: by default false, in this case the union of all the regions in the shape file is masked out. If true, the regions in the shapefiles are masked out separately, generating an auxiliary dimension for the cube for this.

Examples:

• Extract the shape of the river Elbe from a shapefile:

```
extract_shape:
   shapefile: Elbe.shp
   method: contains
```

See also esmvalcore.preprocessor.extract_shape().

8.10.4 extract_point

Extract a single point from the data. This is done using either nearest or linear interpolation.

Returns a cube with the extracted point(s), and with adjusted latitude and longitude coordinates (see below).

Multiple points can also be extracted, by supplying an array of latitude and/or longitude coordinates. The resulting point cube will match the respective latitude and longitude coordinate to those of the input coordinates. If the input coordinate is a scalar, the dimension will be missing in the output cube (that is, it will be a scalar).

Parameters:

- cube: the input dataset cube.
- latitude, longitude: coordinates (as floating point values) of the point to be extracted. Either (or both) can also be an array of floating point values.
- scheme: interpolation scheme: either 'linear' or 'nearest'. There is no default.

8.10.5 zonal_statistics

The function calculates the zonal statistics by applying an operator along the longitude coordinate. This function takes one argument:

• operator: Which operation to apply: mean, std_dev, median, min, max, sum or rms.

See also esmvalcore.preprocessor.zonal_means().

8.10.6 meridional_statistics

The function calculates the meridional statistics by applying an operator along the latitude coordinate. This function takes one argument:

• operator: Which operation to apply: mean, std_dev, median, min, max, sum or rms.

See also esmvalcore.preprocessor.meridional_means().

8.10.7 area_statistics

This function calculates the average value over a region - weighted by the cell areas of the region. This function takes the argument, operator: the name of the operation to apply.

This function can be used to apply several different operations in the horizontal plane: mean, standard deviation, median, variance, minimum, maximum and root mean square.

Note that this function is applied over the entire dataset. If only a specific region, depth layer or time period is required, then those regions need to be removed using other preprocessor operations in advance.

The fx_variables argument specifies the fx variables that the user wishes to input to the function; the user may specify it as a list of variables e.g.

fx_variables: ['areacello', 'volcello']

or as list of dictionaries, with specific variable parameters (they key-value pair may be as specific as a CMOR variable can permit):

The recipe parser wil automatically find the data files that are associated with these variables and pass them to the function for loading and processing.

See also esmvalcore.preprocessor.area_statistics().

8.11 Volume manipulation

The _volume.py module contains the following preprocessor functions:

- extract_volume: Extract a specific depth range from a cube.
- volume_statistics: Calculate the volume-weighted average.
- depth_integration: Integrate over the depth dimension.
- extract_transect: Extract data along a line of constant latitude or longitude.
- extract_trajectory: Extract data along a specified trajectory.

8.11.1 extract_volume

Extract a specific range in the z-direction from a cube. This function takes two arguments, a minimum and a maximum $(z_{\min} \text{ and } z_{\max}, \text{ respectively})$ in the z-direction.

Note that this requires the requested z-coordinate range to be the same sign as the Iris cube. That is, if the cube has z-coordinate as negative, then z_{min} and z_{max} need to be negative numbers.

See also esmvalcore.preprocessor.extract_volume().

8.11.2 volume_statistics

This function calculates the volume-weighted average across three dimensions, but maintains the time dimension.

This function takes the argument: operator, which defines the operation to apply over the volume.

No depth coordinate is required as this is determined by Iris. This function works best when the fx_variables provide the cell volume.

The fx_variables argument specifies the fx variables that the user wishes to input to the function; the user may specify it as a list of variables e.g.

fx_variables: ['areacello', 'volcello']

or as list of dictionaries, with specific variable parameters (they key-value pair may be as specific as a CMOR variable can permit):

The recipe parser wil automatically find the data files that are associated with these variables and pass them to the function for loading and processing.

See also esmvalcore.preprocessor.volume_statistics().

8.11.3 depth_integration

This function integrates over the depth dimension. This function does a weighted sum along the z-coordinate, and removes the z direction of the output cube. This preprocessor takes no arguments.

See also esmvalcore.preprocessor.depth_integration().

8.11.4 extract_transect

This function extracts data along a line of constant latitude or longitude. This function takes two arguments, although only one is strictly required. The two arguments are latitude and longitude. One of these arguments needs to be set to a float, and the other can then be either ignored or set to a minimum or maximum value.

For example, if we set latitude to 0 N and leave longitude blank, it would produce a cube along the Equator. On the other hand, if we set latitude to 0 and then set longitude to [40., 100.] this will produce a transect of the Equator in the Indian Ocean.

See also esmvalcore.preprocessor.extract_transect().

8.11.5 extract_trajectory

This function extract data along a specified trajectory. The three arguments are: latitudes, longitudes and number of point needed for extrapolation number_points.

If two points are provided, the number_points argument is used to set a the number of places to extract between the two end points.

If more than two points are provided, then extract_trajectory will produce a cube which has extrapolated the data of the cube to those points, and number_points is not needed.

Note that this function uses the expensive interpolate method from Iris.analysis.trajectory, but it may be necessary for irregular grids.

See also esmvalcore.preprocessor.extract_trajectory().

8.12 Cycles

The _cycles.py module contains the following preprocessor functions:

• amplitude: Extract the peak-to-peak amplitude of a cycle aggregated over specified coordinates.

8.12.1 amplitude

This function extracts the peak-to-peak amplitude (maximum value minus minimum value) of a field aggregated over specified coordinates. Its only argument is coords, which can either be a single coordinate (given as str) or multiple coordinates (given as list of str). Usually, these coordinates refer to temporal categorised coordinates like *year*, *month*, *day of year*, etc. For example, to extract the amplitude of the annual cycle for every single year in the data, use coords: year; to extract the amplitude of the diurnal cycle for every single day in the data, use coords: [year, day_of_year].

See also esmvalcore.preprocessor.amplitude().

8.13 Detrend

ESMValTool also supports detrending along any dimension using the preprocessor function 'detrend'. This function has two parameters:

- dimension: dimension to apply detrend on. Default: "time"
- method: It can be linear or constant. Default: linear

If method is linear, detrend will calculate the linear trend along the selected axis and subtract it to the data. For example, this can be used to remove the linear trend caused by climate change on some variables is selected dimension is time.

If method is constant, detrend will compute the mean along that dimension and subtract it from the data

See also esmvalcore.preprocessor.detrend().

8.14 Unit conversion

Converting units is also supported. This is particularly useful in cases where different datasets might have different units, for example when comparing CMIP5 and CMIP6 variables where the units have changed or in case of observational datasets that are delivered in different units.

In these cases, having a unit conversion at the end of the processing will guarantee homogeneous input for the diagnostics.

Note: Conversion is only supported between compatible units! In other words, converting temperature units from degC to Kelvin works fine, changing precipitation units from a rate based unit to an amount based unit is not supported at the moment.

See also *esmvalcore.preprocessor.convert_units()*.

8.15 Information on maximum memory required

In the most general case, we can set upper limits on the maximum memory the analysis will require:

 $Ms = (R + N) \times F_{eff} - F_{eff}$ when no multimodel analysis is performed;

Mm = (2R + N) x F_eff - 2F_eff - when multimodel analysis is performed;

where

- Ms: maximum memory for non-multimodel module
- Mm: maximum memory for multimodel module
- R: computational efficiency of module; *R* is typically 2-3
- N: number of datasets
- F_eff: average size of data per dataset where $F_eff = e \times f \times F$ where e is the factor that describes how lazy the data is (e = 1 for fully realized data) and f describes how much the data was shrunk by the immediately previous module, e.g. time extraction, area selection or level extraction; note that for fix_data f relates only to the time extraction, if data is exact in time (no time selection) f = 1 for fix_data so for cases when we deal with a lot of datasets $R + N \setminus approx N$, data is fully realized, assuming an average size of 1.5GB for 10 years of 3D netCDF data, N datasets will require:

 $Ms = 1.5 \times (N - 1) GB$ $Mm = 1.5 \times (N - 2) GB$

As a rule of thumb, the maximum required memory at a certain time for multimodel analysis could be estimated by multiplying the number of datasets by the average file size of all the datasets; this memory intake is high but also assumes that all data is fully realized in memory; this aspect will gradually change and the amount of realized data will decrease with the increase of dask use.

8.16 Other

Miscellaneous functions that do not belong to any of the other categories.

8.16.1 Clip

This function clips data values to a certain minimum, maximum or range. The function takes two arguments:

- minimum: Lower bound of range. Default: None
- maximum: Upper bound of range. Default: None

The example below shows how to set all values below zero to zero.

preprocessors: clip: minimum: 0 maximum: null

Part III

Diagnostic script interfaces

In order to communicate with diagnostic scripts, ESMValCore uses YAML files. The YAML files provided by ESM-ValCore to the diagnostic script tell the diagnostic script the settings that were provided in the recipe and where to find the pre-processed input data. On the other hand, the YAML file provided by the diagnostic script to ESMValCore tells ESMValCore which pre-processed data was used to create what plots. The latter is optional, but needed for recording provenance.

CHAPTER

NINE

PROVENANCE

When ESMValCore (the esmvaltool command) runs a recipe, it will first find all data and run the default preprocessor steps plus any additional preprocessing steps defined in the recipe. Next it will run the diagnostic script defined in the recipe and finally it will store provenance information. Provenance information is stored in the W3C PROV XML format and also plotted in an SVG file for human inspection. In addition to provenance information, a caption is also added to the plots.

CHAPTER

INFORMATION PROVIDED BY ESMVALCORE TO THE DIAGNOSTIC SCRIPT

To provide the diagnostic script with the information it needs to run (e.g. location of input data, various settings), the ESMValCore creates a YAML file called settings.yml and provides the path to this file as the first command line argument to the diagnostic script.

The most interesting settings provided in this file are

Custom settings in the script section of the recipe will also be made available in this file.

There are three directories defined:

- run_dir use this for storing temporary files
- work_dir use this for storing NetCDF files containing the data used to make a plot
- plot_dir use this for storing plots

Finally input_files is a list of YAML files, containing a description of the preprocessed data. Each entry in these YAML files is a path to a preprocessed file in NetCDF format, with a list of various attributes. An example preprocessor metadata.yml file could look like this:

```
? /path/to/recipe_output/preproc/diagnostic_name/pr/CMIP5_GFDL-ESM2G_Amon_historical_
→r1i1p1_T2Ms_pr_2000-2002.nc

CHAPTER

ELEVEN

INFORMATION PROVIDED BY THE DIAGNOSTIC SCRIPT TO ESMVALCORE

After the diagnostic script has finished running, ESMValCore will try to store provenance information. In order to link the produced files to input data, the diagnostic script needs to store a YAML file called diagnostic_provenance.yml in it's run_dir.

For output file produced by the diagnostic script, there should be an entry in the diagnostic_provenance.yml file. The name of each entry should be the path to the output file. Each file entry should at least contain the following items

- ancestors a list of input files used to create the plot
- caption a caption text for the plot
- plot_file if the diagnostic also created a plot file, e.g. in .png format.

Each file entry can also contain items from the categories defined in the file <code>esmvaltool/config_references</code>. yml. The short entries will automatically be replaced by their longer equivalent in the final provenance records. It is possible to add custom provenance information by adding custom items to entries.

An example diagnostic_provenance.yml file could look like this

```
? /path/to/recipe_output/work/diagnostic_name/script_name/CMIP5_GFDL-ESM2G_Amon_
→historical_r1i1p1_T2Ms_pr_2000-2002_mean.nc
: ancestors:[/path/to/recipe_output/preproc/diagnostic_name/pr/CMIP5_GFDL-ESM2G_Amon_
→historical_r1i1p1_T2Ms_pr_2000-2002.nc]
 authors: [andela_bouwe, righi_mattia]
 caption: Average Precipitation between 2000 and 2002 according to GFDL-ESM2G.
 domains: [global]
 plot_file: /path/to/recipe_output/plots/diagnostic_name/script_name/CMIP5_GFDL,
→ESM2G_Amon_historical_r1i1p1_T2Ms_pr_2000-2002_mean.png
 plot_type: zonal
 references: [acknow_project]
 statistics: [mean]
? /path/to/recipe_output/work/diagnostic_name/script_name/CMIP5_MPI-ESM-LR_Amon_
→historical_r1i1p1_T2Ms_pr_2000-2002_mean.nc
: ancestors: [/path/to/recipe_output/preproc/diagnostic_name/pr/CMIP5_MPI-ESM-LR_Amon_
→historical_r1i1p1_T2Ms_pr_2000-2002.nc]
 authors: [andela_bouwe, righi_mattia]
 caption: Average Precipitation between 2000 and 2002 according to MPI-ESM-LR.
 domains: [global]
 plot_file: /path/to/recipe_output/plots/diagnostic_name/script_name/CMIP5_MPI-ESM-
→LR_Amon_historical_r1i1p1_T2Ms_pr_2000-2002_mean.png
 plot_type: zonal
```

(continues on next page)

(continued from previous page)

```
references: [acknow_project]
statistics: [mean]
```

You can check whether your diagnostic script successfully provided the provenance information to the ESMValCore by verifying that

- for each output file in the work_dir, a file with the same name, but ending with _provenance.xml is created
- any NetCDF files created by your diagnostic script contain a 'provenance' global attribute
- any PNG plots created by your diagnostic script contain the provenance information in the 'Image History' attribute

Note that this information is included automatically by ESMValCore if the diagnostic script provides the required diagnostic_provenance.yml file.

Part IV

Development

TWELVE

DATASET FIXES

Some (model) datasets contain (known) errors that would normally prevent them from being processed correctly by the ESMValTool. The errors can be in the metadata describing the dataset and/or in the actual data. Typical examples of such errors are missing or wrong attributes (e.g. attribute ''units'' says 1e-9 but data are actually in 1e-6), missing or mislabeled coordinates (e.g. ''lev'' instead of ''plev'' or missing coordinate bounds like ''lat_bnds'') or problems with the actual data (e.g. cloud liquid water only instead of sum of liquid + ice as specified by the CMIP data request).

The ESMValTool can apply on the fly fixes to data sets that have known errors that can be fixed automatically.

Note: CMORization as a fix. As of early 2020, we've started implementing CMORization as fixes for observational datasets. Previously, CMORization was an additional function implemented in ESMValTool. This meant that users always had to store 2 copies of their observational data: both raw and CMORized. Implementing CMORization as a fix removes this redundancy, as the fixes are applied 'on the fly' when running a recipe. **ERA5** is the first dataset for which this 'CMORization on the fly' is supported. For more information about CMORization, see: Contributing a CMORizing script for an observational dataset.

12.1 Fix structure

Fixes are Python classes stored in <code>esmvalcore/cmor/_fixes/[PROJECT]/[DATASET]</code>.py that derive from <code>esmvalcore.cmor._fixes.fix.Fix</code> and are named after the short name of the variable they fix. You can use the name <code>AllVars</code> if you want the fix to be applied to the whole dataset

Warning: Be careful to replace any – with _ in your dataset name. We need this replacement to have proper python module names.

The fixes are automatically loaded and applied when the dataset is preprocessed.

12.2 Fixing a dataset

To illustrate the process of creating a fix we are going to construct a new one from scratch for a fictional dataset. We need to fix a CMIPX model called PERFECT-MODEL that is reporting a missing latitude coordinate for variable tas.

12.2.1 Check the output

Next to the error message, you should see some info about the iris cube: size, coordinates. In our example it looks like this:

```
air_temperature/ (K) (time: 312; altitude: 90; longitude: 180)
   Dimension coordinates:
        time
                                                    х
                                                                    _
        altitude
                                                    _
                                                                    х
                                                                                     _
        longitude
                                                                                     х
   Auxiliary coordinates:
        day_of_month
                                                    Х
        day_of_year
                                                    Х
        month_number
                                                    х
        year
                                                    Х
   Attributes:
        {'cmor_table': 'CMIPX', 'mip': 'Amon', 'short_name': 'tas', 'frequency': 'mon
\rightarrow ' })
```

So now the mistake is clear: the latitude coordinate is badly named and the fix should just rename it.

12.2.2 Create the fix

We start by creating the module file. In our example the path will be <code>esmvalcore/cmor/_fixes/CMIPX/</code> PERFECT_MODEL.py. If it already exists just add the class to the file, there is no limit in the number of fixes we can have in any given file.

Then we have to create the class for the fix deriving from esmvalcore.cmor._fixes.Fix

```
"""Fixes for PERFECT-MODEL."""
from esmvalcore.cmor.fix import Fix
class tas(Fix):
    """Fixes for tas variable.""""
```

Next we must choose the method to use between the ones offered by the Fix class:

- fix_file : should be used only to fix errors that prevent data loading. As a rule of thumb, you should only use it if the execution halts before reaching the checks.
- fix_metadata : you want to change something in the cube that is not the data (e.g variable or coordinate names, data units).
- fix_data: you need to fix the data. Beware: coordinates data values are part of the metadata.

In our case we need to rename the coordinate altitude to latitude, so we will implement the fix_metadata method:

```
"""Fixes for PERFECT-MODEL."""
from esmvalcore.cmor.fix import Fix
class tas(Fix):
    """Fixes for tas variable.""""
    def fix_metadata(self, cubes):
        """
        Fix metadata for tas.
```

(continues on next page)

(continued from previous page)

```
Fix the name of the latitude coordinate, which is called altitude
in the original file.
# Sometimes Iris will interpret the data as multiple cubes.
# Good CMOR datasets will only show one but we support the
# multiple cubes case to be able to fix the errors that are
# leading to that extra cubes.
# In our case this means that we can safely assume that the
# tas cube is the first one
tas\_cube = cubes[0]
latitude = tas_cube.coord('altitude')
# Fix the names. Latitude values, units and
latitude.short_name = 'lat'
latitude.standard name = 'latitude'
latitude.long_name = 'latitude'
return cubes
```

This will fix the error. The next time you run ESMValTool you will find that the error is fixed on the fly and, hopefully, your recipe will run free of errors.

Sometimes other errors can appear after you fix the first one because they were hidden by it. In our case, the latitude coordinate could have bad units or values outside the valid range for example. Just extend your fix to address those errors.

12.2.3 Finishing

Chances are that you are not the only one that wants to use that dataset and variable. Other users could take advantage of your fixes as soon as possible. Please, create a separated pull request for the fix and submit it.

It will also be very helpful if you just scan a couple of other variables from the same dataset and check if they share this error. In case that you find that it is a general one, you can change the fix name to AllVars so it gets executed for all variables in the dataset. If you find that this is shared only by a handful of similar vars you can just make the fix for those new vars derive from the one you just created:

```
"""Fixes for PERFECT-MODEL."""
from esmvalcore.cmor.fix import Fix
class tas(Fix):
    """Fixes for tas variable."""
   def fix_metadata(self, cubes):
        Fix metadata for tas.
        Fix the name of the latitude coordinate, which is called altitude
        in the original file.
        # Sometimes Iris will interpret the data as multiple cubes.
        # Good CMOR datasets will only show one but we support the
        # multiple cubes case to be able to fix the errors that are
        # leading to that extra cubes.
        # In our case this means that we can safely assume that the
        # tas cube is the first one
       tas\_cube = cubes[0]
```

(continues on next page)

(continued from previous page)

```
latitude = tas_cube.coord('altitude')

# Fix the names. Latitude values, units and
latitude.short_name = 'lat'
latitude.standard_name = 'latitude'
latitude.long_name = 'latitude'
return cubes

class ps(tas):
    """Fixes for ps variable."""
```

12.3 Common errors

The above example covers one of the most common cases: variables / coordinates that have names that do not match the expected. But there are some others that use to appear frequently. This section describes the most common cases.

12.3.1 Bad units declared

It is quite common that a variable declares to be using some units but the data is stored in another. This can be solved by overwriting the units attribute with the actual data units.

```
def fix_metadata(self, cubes):
    cube.units = 'real_units'
```

Detecting this error can be tricky if the units are similar enough. It also has a good chance of going undetected until you notice strange results in your diagnostic.

For the above example, it can be useful to access the variable definition and associated coordinate definitions as provided by the CMOR table. For example:

```
def fix_metadata(self, cubes):
    cube.units = self.vardef.units
```

To learn more about what is available in these definitions, see: <code>esmvalcore.cmor.table.VariableInfo</code> and <code>esmvalcore.cmor.table.CoordinateInfo</code>.

12.3.2 Coordinates missing

Another common error is to have missing coordinates. Usually it just means that the file does not follow the CFconventions and Iris can therefore not interpret it.

If this is the case, you should see a warning from the ESMValTool about discarding some cubes in the fix metadata step. Just before that warning you should see the full list of cubes as read by Iris. If that list contains your missing coordinate you can create a fix for this model:

```
def fix_metadata(self, cubes):
    coord_cube = cubes.extract_strict('COORDINATE_NAME')
    # Usually this will correspond to an auxiliary coordinate
    # because the most common error is to forget adding it to the
    # coordinates attribute
```

(continues on next page)

(continued from previous page)

```
coord = iris.coords.AuxCoord(
    coord_cube.data,
    var_name=coord_cube.var_name,
    standard_name=coord_cube.standard_name,
    long_name=coord_cube.long_name,
    units=coord_cube.units,
}
# It may also have bounds as another cube
coord.bounds = cubes.extract_strict('BOUNDS_NAME').data
data_cube = cubes.extract_strict('VAR_NAME')
data_cube.add_aux_coord(coord, DIMENSIONS_INDEX_TUPLE)
return [data_cube]
```

12.4 Customizing checker strictness

The data checker classifies its issues using four different levels of severity. From highest to lowest:

- CRITICAL: issues that most of the time will have severe consequences.
- ERROR: issues that usually lead to unexpected errors, but can be safely ignored sometimes.
- WARNING: something is not up to the standard but is unlikely to have consequences later.
- DEBUG: any info that the checker wants to communicate. Regardless of checker strictness, those will always be reported as debug messages.

Users can have control about which levels of issues are interpreted as errors, and therefore make the checker fail or warnings or debug messages. For this purpose there is an optional command line option *–check-level* that can take a number of values, listed below from the lowest level of strictness to the highest:

- ignore: all issues, regardless of severity, will be reported as warnings. Checker will never fail. Use this at your own risk.
- relaxed: only CRITICAL issues are treated as errors. We recommend not to rely on this mode, although it can be useful if there are errors preventing the run that you are sure you can manage on the diagnostics or that will not affect you.
- default: fail if there are any CRITICAL or ERROR issues (DEFAULT); Provides a good measure of safety.
- strict: fail if there are any warnings, this is the highest level of strictness. Mostly useful for checking datasets that you have produced, to be sure that future users will not be distracted by inoffensive warnings.

THIRTEEN

VARIABLE DERIVATION

The variable derivation module allows to derive variables which are not in the CMIP standard data request using standard variables as input. All derivations scripts are located in ESMValCore/esmvalcore/preprocessor/_derive/. A typical example looks like this:

```
"""Derivation of variable `dummv`."""
from ._baseclass import DerivedVariableBase
class DerivedVariable(DerivedVariableBase):
    """Derivation of variable `dummy`."""
    @staticmethod
    def required(project):
        """Declare the variables needed for derivation."""
       mip = 'fx'
        if project == 'CMIP6':
           mip = 'Ofx'
        required = [
            {'short_name': 'var_a'},
            {'short_name': 'var_b', 'mip': mip, 'optional': True},
        1
        return required
    @staticmethod
   def calculate(cubes):
        """Compute `dummy`."""
        # `cubes` is a CubeList containing all required variables.
        cube = do_something_with(cubes)
        # Return single cube at the end
        return cube
```

The static function required (project) returns a list of dict containing all required variables for deriving the derived variable. Its only argument is the project of the specific dataset. In this particular example script, the derived variable dummy is derived from var_a and var_b. It is possible to specify arbitrary attributes for each required variable, e.g. var_b uses the mip fx (or Ofx in the case of CMIP6) instead of the original one of dummy. Note that you can also declare a required variable as optional=True, which allows the skipping of this particular variable during data extraction. For example, this is useful for fx variables which are often not available for observational datasets. Otherwise, the tool will fail if not all required variables are available for all datasets.

The actual derivation takes place in the static function calculate (cubes) which returns a single cube containing the derived variable. Its only argument cubes is a CubeList containing all required variables.

Part V

Contributions are very welcome

We greatly value contributions of any kind. Contributions could include, but are not limited to documentation improvements, bug reports, new or improved code, scientific and technical code reviews, infrastructure improvements, mailing list and chat participation, community help/building, education and outreach. We value the time you invest in contributing and strive to make the process as easy as possible. If you have suggestions for improving the process of contributing, please do not hesitate to propose them.

If you have a bug or other issue to report or just need help, please open an issue on the issues tab on the ESMValCore github repository.

If you would like to contribute a new preprocessor function, derived variable, fix for a dataset, or another new feature, please discuss your idea with the development team before getting started, to avoid double work and/or disappointment later. A good way to do this is to open an issue on GitHub.

To get started developing, follow the instructions below. For help with common new features, please have a look at *Development*.

FOURTEEN

GETTING STARTED

To install for development, follow the instructions in *Installation*.

FIFTEEN

RUNNING TESTS

Go to the directory where the repository is cloned and run <code>pytest</code>. Optionally you can skip tests which require additional dependencies for supported diagnostic script languages by adding -m 'not installation' to the previous command. Tests will also be run automatically by CircleCI.

SIXTEEN

CODE STYLE

To increase the readability and maintainability or the ESMValCore source code, we aim to adhere to best practices and coding standards. All pull requests are reviewed and tested by one or more members of the core development team. For code in all languages, it is highly recommended that you split your code up in functions that are short enough to view without scrolling.

We include checks for Python and yaml files, which are described in more detail in the sections below. This includes checks for invalid syntax and formatting errors. Pre-commit is a handy tool that can run all of these checks automatically. It knows knows which tool to run for each filetype, and therefore provides a simple way to check your code!

16.1 Pre-commit

To run pre-commit on your code, go to the ESMValCore directory (cd ESMValCore) and run

pre-commit run

By default, pre-commit will only run on the files that have been changed, meaning those that have been staged in git (i.e. after git add your_script.py).

To make it only check some specific files, use

pre-commit run --files your_script.py

or

```
pre-commit run --files your_script.R
```

Alternatively, you can configure pre-commit to run on the staged files before every commit (i.e. git commit), by installing it as a git hook using

pre-commit install

Pre-commit hooks are used to inspect the code that is about to be committed. The commit will be aborted if files are changed or if any issues are found that cannot be fixed automatically. Some issues cannot be fixed (easily), so to bypass the check, run

```
git commit --no-verify
```

or

```
git commit -n
```

or uninstall the pre-commit hook

pre-commit uninstall

16.2 Python

The standard document on best practices for Python code is PEP8 and there is PEP257 for documentation. We make use of numpy style docstrings to document Python functions that are visible on readthedocs.

Most formatting issues in Python code can be fixed automatically by running the commands

```
isort some_file.py
```

to sort the imports in the standard way using isort and

yapf -i some_file.py

to add/remove whitespace as required by the standard using yapf,

```
docformatter -i your_script.py
```

to run docformatter which helps formatting the doc strings (such as line length, spaces).

To check if your code adheres to the standard, go to the directory where the repository is cloned, e.g. cd ESMValCore, and run prospector

prospector esmvaltool/diag_scripts/your_diagnostic/your_script.py

Run

```
python setup.py lint
```

to see the warnings about the code style of the entire project.

We use flake8 on CircleCI to automatically check that there are no formatting mistakes and Codacy for monitoring (Python) code quality. Running prospector locally will give you quicker and sometimes more accurate results.

16.3 YAML

Please use yamllint to check that your YAML files do not contain mistakes.

16.4 Any text file

A generic tool to check for common spelling mistakes is codespell.

CHAPTER SEVENTEEN

DOCUMENTATION

17.1 What should be documented

Any code documentation that is visible on readthedocs should be well written and adhere to the standards for documentation for the respective language. Note that there is no need to write extensive documentation for functions that are not visible on readthedocs. However, adding a one line docstring describing what a function does is always a good idea. When making changes/introducing a new preprocessor function, also update the preprocessor documentation.

17.2 How to build the documentation locally

Go to the directory where the repository is cloned and run

python setup.py build_sphinx -Ea

Make sure that your newly added documentation builds without warnings or errors.

EIGHTEEN

BRANCHES, PULL REQUESTS AND CODE REVIEW

The default git branch is master. Use this branch to create a new feature branch from and make a pull request against. This page offers a good introduction to git branches, but it was written for BitBucket while we use GitHub, so replace the word BitBucket by GitHub whenever you read it.

It is recommended that you open a draft pull request early, as this will cause CircleCI to run the unit tests and Codacy to analyse your code. It's also easier to get help from other developers if your code is visible in a pull request.

You can view the results of the automatic checks below your pull request. If one of the tests shows a red cross instead of a green approval sign, please click the link and try to solve the issue. Note that this kind of automated checks make it easier to review code, but they are not flawless, so occasionally Codacy will report false positives.

18.1 Contributing to the ESMValCore package

Contributions to ESMValCore should

- Preferably be covered by unit tests. Unit tests are mandatory for new preprocessor functions or modifications to existing functions. If you do not know how to start with writing unit tests, let us know in a comment on the pull request and a core development team member will try to help you get started.
- Be accompanied by appropriate documentation.
- Introduce no new issues on Codacy.

18.2 List of authors

If you make a (significant) contribution to ESMValCore, please add your name to the list of authors in CITATION.cff and regenerate the file .zenodo.json by running the command

```
pip install cffconvert
cffconvert --ignore-suspect-keys --outputformat zenodo --outfile .zenodo.json
```

NINETEEN

HOW TO MAKE A RELEASE

To make a new release of the package, follow these steps:

19.1 1. Check that the nightly build on CircleCl was successful

Check the nightly build on CircleCI. All tests should pass before making a release.

19.2 2. Make a pull request to increase the version number

The version number is stored in esmvalcore/_version.py, package/meta.yaml, CITATION.cff. Make sure to update all files. See https://semver.org for more information on choosing a version number.

19.3 3. Make the release on GitHub

Click the releases tab and draft the new release. Do not forget to tick the pre-release box for a beta release. Use the script esmvalcore/utils/draft_release_notes.py to create a draft version of the release notes and edit those.

19.4 4. Create and upload the Conda package

Follow these steps to create a new conda package:

- Check out the tag corresponding to the release, e.g. git checkout v2.0.0b6
- Edit package/meta.yaml and uncomment the lines starting with git_rev and git_url, remove the line starting with path in the source section.
- Activate the base environment conda activate base
- Run conda build package -c conda-forge -c esmvalgroup to build the conda package
- If the build was successful, upload the package to the esmvalgroup conda channel, e.g. anaconda upload --user esmvalgroup /path/to/conda/conda-bld/noarch/esmvalcore-2.0. 0b6-py_0.tar.bz2.

Part VI

ESMValTool Core API Reference

ESMValCore is mostly used as a commandline tool. However, it is also possibly to use (parts of) ESMValTool as a library. This section documents the public API of ESMValCore.

TWENTY

CMOR FUNCTIONS

CMOR module.

20.1 Checking compliance

Module for checking iris cubes against their CMOR definitions.

Classes:

<pre>CMORCheck(cube, var_info[, frequency,])</pre>	Class used to check the CMOR-compliance of the data.
CheckLevels(value)	Level of strictness of the checks.

Exceptions:

CMORCheckError	Exception raised when a cube does not pass the
	CMORCheck.

Functions:

<pre>cmor_check(cube, cmor_table, mip,)</pre>	Check if cube conforms to variable's CMOR definiton.	
<pre>cmor_check_data(cube, cmor_table, mip,)</pre>	Check if data conforms to variable's CMOR definiton.	
<pre>cmor_check_metadata(cube, cmor_table, mip,</pre>	Check if metadata conforms to variable's CMOR defini-	
)	ton.	

<pre>class esmvalcore.cmor.check.CMORCheck</pre>	(cube,	var_info,		fre-
	quency=None,	fail_on_	_error=	=False,
	check_level= <checkl< th=""><th>evels.DEFAULT:</th><th>3>,</th><th>auto-</th></checkl<>	evels.DEFAULT:	3>,	auto-
	matic_fixes=False)			

Bases: object

Class used to check the CMOR-compliance of the data.

It can also fix some minor errors and does some minor data homogeneization:

Parameters

- **cube** (*iris.cube.Cube*:) Iris cube to check.
- **var_info** (*variables_info*. *VariableInfo*) Variable info to check.
- **frequency** (*str*) Expected frequency for the data.

- **fail_on_error** (*bool*) If true, CMORCheck stops on the first error. If false, it collects all possible errors before stopping.
- **automatic_fixes** (*bool*) If True, CMORCheck will try to apply automatic fixes for any detected error, if possible.
- check_level (CheckLevels) Level of strictness of the checks.

frequency

Expected frequency for the data.

Type str

Methods:

check_data([logger])	Check the cube data.
check_metadata([logger])	Check the cube metadata.
has_debug_messages()	Check if there are reported debug messages.
has_errors()	Check if there are reported errors.
has_warnings()	Check if there are reported warnings.
report(level, message, *args)	Generic method to report a message from the checker
report_critical(message, *args)	Report an error.
<pre>report_debug_message(message, *args)</pre>	Report a debug message.
report_debug_messages()	Report detected debug messages to the given logger.
report_error(message, *args)	Report a normal error.
report_errors()	Report detected errors.
<pre>report_warning(message, *args)</pre>	Report a warning level error.
report_warnings()	Report detected warnings to the given logger.

check_data(logger=None)

Check the cube data.

Performs all the tests that require to have the data in memory. Assumes that metadata is correct, so you must call check_metadata prior to this.

It will also report some warnings in case of minor errors.

Parameters logger (logging.Logger) - Given logger.

Raises *CMORCheckError* – If errors are found. If fail_on_error attribute is set to True, raises as soon as an error is detected. If set to False, it perform all checks and then raises.

check_metadata(logger=None)

Check the cube metadata.

Perform all the tests that do not require to have the data in memory.

It will also report some warnings in case of minor errors and homogenize some data:

- Equivalent calendars will all default to the same name.
- Time units will be set to days since 1850-01-01

Parameters logger (logging.Logger) - Given logger.

Raises *CMORCheckError* – If errors are found. If fail_on_error attribute is set to True, raises as soon as an error is detected. If set to False, it perform all checks and then raises.

has_debug_messages()

Check if there are reported debug messages.

Returns True if there are pending debug messages, False otherwise.

Return type bool

has_errors()

Check if there are reported errors.

Returns True if there are pending errors, False otherwise.

Return type bool

has_warnings()

Check if there are reported warnings.

Returns True if there are pending warnings, False otherwise.

Return type bool

report (*level*, *message*, **args*)

Generic method to report a message from the checker

Parameters

- level (CheckLevels) Message level
- **message** (*str*) Message to report
- args String format args for the message

Raises CMORCheckError – If fail on error is set, it is thrown when registering an error message

report_critical (message, *args)

Report an error.

If fail_on_error is set to True, raises automatically. If fail_on_error is set to False, stores it for later reports.

Parameters

- **message** (*str: unicode*) Message for the error.
- ***args** arguments to format the message string.
- report_debug_message(message, *args)

Report a debug message.

Parameters

- **message** (*str: unicode*) Message for the debug logger.
- ***args** arguments to format the message string

report_debug_messages()

Report detected debug messages to the given logger.

Parameters logger (logging.Logger) – Given logger.

report_error (message, *args)

Report a normal error.

Parameters

- **message** (*str: unicode*) Message for the error.
- ***args** arguments to format the message string.

report_errors()

Report detected errors.

Raises CMORCheckError – If any errors were reported before calling this method.

report_warning (message, *args)

Report a warning level error.

Parameters

• message (str: unicode) – Message for the warning.

• ***args** – arguments to format the message string.

report_warnings()

Report detected warnings to the given logger.

Parameters logger (logging.Logger) – Given logger

exception esmvalcore.cmor.check.CMORCheckError

Bases: Exception

Exception raised when a cube does not pass the CMORCheck.

args

```
with_traceback()
```

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

class esmvalcore.cmor.check.CheckLevels(value)

Bases: enum.IntEnum

Level of strictness of the checks.

- DEBUG

Type Report any debug message that the checker wants to communicate.

- STRICT

Type Fail if there are warnings regarding compliance of CMOR standards.

- DEFAULT

Type Fail if cubes present any discrepancy with CMOR standards.

- RELAXED

Type Fail if cubes present severe discrepancies with CMOR standards.

- IGNORE

Type Do not fail for any discrepancy with CMOR standards.

Attributes:

DEBUG			
DEFAULT	 	 	
IGNORE			
RELAXED			
STRICT			

DEBUG = 1

DEFAULT = 3 IGNORE = 5 RELAXED = 4 STRICT = 2

esmvalcore.cmor.check.**cmor_check**(*cube*, *cmor_table*, *mip*, *short_name*, *frequency*, *check_level*) Check if cube conforms to variable's CMOR definiton.

Equivalent to calling cmor_check_metadata and cmor_check_data consecutively.

Parameters

- cube (*iris.cube.Cube*) Data cube to check.
- **cmor_table** (*basestring*) **CMOR** definitions to use.
- **mip** Variable's mip.
- **short_name** (*basestring*) Variable's short name.
- **frequency** (basestring) Data frequency.
- check_level (enum. IntEnum) Level of strictness of the checks.

Check if data conforms to variable's CMOR definiton.

The checks performed at this step require the data in memory.

Parameters

- **cube** (*iris.cube.Cube*) Data cube to check.
- **cmor_table** (*basestring*) **CMOR** definitions to use.
- **mip** Variable's mip.
- **short_name** (*basestring*) Variable's short name
- frequency (basestring) Data frequency
- check_level (CheckLevels) Level of strictness of the checks.

Check if metadata conforms to variable's CMOR definiton.

None of the checks at this step will force the cube to load the data.

Parameters

- **cube** (*iris.cube.Cube*) Data cube to check.
- **cmor_table** (*basestring*) **CMOR** definitions to use.
- **mip** Variable's mip.
- **short_name** (*basestring*) Variable's short name.
- **frequency** (*basestring*) Data frequency.
- check_level (CheckLevels) Level of strictness of the checks.

20.2 Automatically fixing issues

Apply automatic fixes for known errors in cmorized data

All functions in this module will work even if no fixes are available for the given dataset. Therefore is recommended to apply them to all variables to be sure that all known errors are fixed.

Functions:

<pre>fix_data(cube, short_name, project, dataset, mip)</pre>	Fix cube data if fixes add present and check it anyway.
<pre>fix_file(file, short_name, project, dataset,)</pre>	Fix files before ESMValTool can load them.
<pre>fix_metadata(cubes, short_name, project,)</pre>	Fix cube metadata if fixes are required and check it any-
	way.

Fix cube data if fixes add present and check it anyway.

This method assumes that metadata is already fixed and checked.

This method collects all the relevant fixes for a given variable, applies them and checks resulting cube (or the original if no fixes were needed) metadata to ensure that it complies with the standards of its project CMOR tables.

Parameters

- cube (iris.cube.Cube) Cube to fix
- **short_name** (*str*) Variable's short name
- project (str)-
- dataset (*str*) -
- mip (str) Variable's MIP
- **frequency** (*str*, *optional*) Variable's data frequency, if available
- check_levels) Level of strictness of the checks. Set to default.

Returns Fixed and checked cube

Return type iris.cube.Cube

Raises CMORCheckError – If the checker detects errors in the data that it can not fix.

esmvalcore.cmor.fix.fix_file(file, short_name, project, dataset, mip, output_dir)
Fix files before ESMValTool can load them.

This fixes are only for issues that prevent iris from loading the cube or that cannot be fixed after the cube is loaded.

Original files are not overwritten.

Parameters

- **file** (*str*) Path to the original file
- **short_name** (*str*) Variable's short name
- project (str)-
- dataset (str)-
- **output_dir** (*str*) Output directory for fixed files

Returns Path to the fixed file

Return type str

Fix cube metadata if fixes are required and check it anyway.

This method collects all the relevant fixes for a given variable, applies them and checks the resulting cube (or the original if no fixes were needed) metadata to ensure that it complies with the standards of its project CMOR tables.

Parameters

- cubes (iris.cube.CubeList) Cubes to fix
- **short_name** (*str*) Variable's short name
- project (str)-
- dataset (str) -
- mip (str) Variable's MIP
- frequency (str, optional) Variable's data frequency, if available
- check_level (CheckLevels) Level of strictness of the checks. Set to default.

Returns Fixed and checked cube

Return type iris.cube.Cube

Raises CMORCheckError – If the checker detects errors in the metadata that it can not fix.

20.3 Functions for fixing issues

Functions for fixing specific issues with datasets.

Functions:

<pre>add_plev_from_altitude(cube)</pre>	Add pressure level coordinate from altitude coordinate.
add_sigma_factory(cube)	Add factory for atmosphere_sigma_coordinate.

esmvalcore.cmor.fixes.add_plev_from_altitude (*cube*) Add pressure level coordinate from altitude coordinate.

Parameters cube (iris.cube.Cube) - Input cube.

Raises ValueError – cube does not contain coordinate altitude.

```
esmvalcore.cmor.fixes.add_sigma_factory(cube)
Add factory for atmosphere_sigma_coordinate.
```

Parameters cube (iris.cube.Cube) - Input cube.

Raises ValueError	_	cube	does	not	contain	coordinate
atmosphere_sigma	_coor	dinate.				

20.4 Using CMOR tables

CMOR information reader for ESMValTool.

Read variable information from CMOR 2 and CMOR 3 tables and make it easily available for the other components of ESMValTool

Classes:

<pre>CMIP3Info(cmor_tables_path[, default,])</pre>	Class to read CMIP3-like data request.
<pre>CMIP5Info(cmor_tables_path[, default,])</pre>	Class to read CMIP5-like data request.
<pre>CMIP6Info(cmor_tables_path[, default,])</pre>	Class to read CMIP6-like data request.
CoordinateInfo(name)	Class to read and store coordinate information.
CustomInfo([cmor_tables_path])	Class to read custom var info for ESMVal.
InfoBase(default, alt_names, strict)	Base class for all table info classes.
JsonInfo()	Base class for the info classes.
TableInfo(*args, **kwargs)	Container class for storing a CMOR table.
<pre>VariableInfo(table_type, short_name)</pre>	Class to read and store variable information.

Data:

```
CMOR_TABLES
```

CMOR info objects.

Functions:

<pre>get_var_info(project, mip, short_name)</pre>	Get variable information.
<pre>read_cmor_tables([cfg_developer])</pre>	Read cmor tables required in the configuration.

class esmvalcore.cmor.table.**CMIP3Info**(*cmor_tables_path*, *default=None*, *alt_names=None*,

strict=True)
Bases: esmvalcore.cmor.table.CMIP5Info

Class to read CMIP3-like data request.

Parameters

- **cmor_tables_path** (*basestring*) Path to the folder containing the Tables folder with the json files
- **default** (*object*) Default table to look variables on if not found
- **strict** (bool) If False, will look for a variable in other tables if it can not be found in the requested one

Methods:

get_table(table)			Search and return the table info.	
get_variable(table_name,	short_name[,	de-	Search and return the variable info.	
rived])				

get_table(table)

Search and return the table info.

```
Parameters table (basestring) – Table name
```

Returns Return the TableInfo object for the requested table if found, returns None if not

Return type TableInfo

get_variable (*table_name*, *short_name*, *derived=False*) Search and return the variable info.

Parameters

- table_name (basestring) Table name
- **short_name** (*basestring*) Variable's short name
- **derived** (*bool*, *optional*) Variable is derived. Info retrieval for derived variables always look on the default tables if variable is not find in the requested table

Returns Return the VariableInfo object for the requested variable if found, returns None if not

Return type VariableInfo

Bases: esmvalcore.cmor.table.InfoBase

Class to read CMIP5-like data request.

Parameters

- **cmor_tables_path** (*basestring*) Path to the folder containing the Tables folder with the json files
- default (object) Default table to look variables on if not found
- **strict** (*bool*) If False, will look for a variable in other tables if it can not be found in the requested one

Methods:

```
get_table(table)Search and return the table info.get_variable(table_name, short_name[, de-<br/>rived])Search and return the variable info.
```

get_table(table)

Search and return the table info.

Parameters table (basestring) - Table name

Returns Return the TableInfo object for the requested table if found, returns None if not

Return type TableInfo

get_variable (*table_name*, *short_name*, *derived=False*) Search and return the variable info.

Parameters

- table_name (basestring) Table name
- **short_name** (*basestring*) Variable's short name
- **derived** (*bool*, *optional*) Variable is derived. Info retrieval for derived variables always look on the default tables if variable is not find in the requested table

Returns Return the VariableInfo object for the requested variable if found, returns None if not

Return type VariableInfo

Bases: esmvalcore.cmor.table.InfoBase

Class to read CMIP6-like data request.

This uses CMOR 3 json format

Parameters

- **cmor_tables_path** (*basestring*) Path to the folder containing the Tables folder with the json files
- default (object) Default table to look variables on if not found
- **strict** (*bool*) If False, will look for a variable in other tables if it can not be found in the requested one

Methods:

```
      get_table(table)
      Search and return the table info.

      get_variable(table_name, short_name[, de-
rived])
      Search and return the variable info.
```

get_table(table)

Search and return the table info.

Parameters table (basestring) - Table name

Returns Return the TableInfo object for the requested table if found, returns None if not

Return type TableInfo

get_variable (*table_name*, *short_name*, *derived=False*) Search and return the variable info.

Parameters

- table_name (basestring) Table name
- short_name (basestring) Variable's short name
- **derived** (*bool*, *optional*) Variable is derived. Info retrieval for derived variables always look on the default tables if variable is not find in the requested table

Returns Return the VariableInfo object for the requested variable if found, returns None if not

Return type VariableInfo

esmvalcore.cmor.table.CMOR_TABLES = {'CMIP3': <esmvalcore.cmor.table.CMIP3Info object>, '(CMOR info objects.

Type dict of str, obj

class esmvalcore.cmor.table.CoordinateInfo(name) Bases: esmvalcore.cmor.table.JsonInfo

Class to read and store coordinate information.

Attributes:

axis	Axis
long_name	Long name

continues on next page

must_have_bounds	Whether bounds are required on this dimension
out_name	Out name
requested	Values requested
standard_name	Standard name
stored_direction	Direction in which the coordinate increases
units	Units
valid_max	Maximum allowed value
valid_min	Minimum allowed value
value	Coordinate value
var_name	Short name

Table 14 – continued from previous page

Methods:

read_json(json_data) Read coordinate information from json.

axis

Axis

long_name

Long name

must_have_bounds

Whether bounds are required on this dimension

out_name

Out name

This is the name of the variable in the file

read_json (json_data)

Read coordinate information from json.

Non-present options will be set to empty

Parameters json_data (*dict*) – dictionary created by the json reader containing coordinate information

requested

Values requested

standard_name

Standard name

stored_direction

Direction in which the coordinate increases

units

Units

valid_max

Maximum allowed value

valid_min

Minimum allowed value

value

Coordinate value

var_name Short name

class esmvalcore.cmor.table.CustomInfo(cmor_tables_path=None)
Bases: esmvalcore.cmor.table.CMIP5Info

Class to read custom var info for ESMVal.

Parameters cmor_tables_path (*basestring or None*) – Full path to the table or name for the table if it is present in ESMValTool repository

Methods:

get_table(table)	Search and return the table info.
<pre>get_variable(table, short_name[, derived])</pre>	Search and return the variable info.

get_table(table)

Search and return the table info.

Parameters table (basestring) - Table name

Returns Return the TableInfo object for the requested table if found, returns None if not

Return type TableInfo

get_variable (table, short_name, derived=False)

Search and return the variable info.

Parameters

- **table** (*basestring*) **Table** name
- **short_name** (*basestring*) Variable's short name
- **derived** (*bool*, *optional*) Variable is derived. Info retrieval for derived variables always look on the default tables if variable is not find in the requested table

Returns Return the VariableInfo object for the requested variable if found, returns None if not

Return type VariableInfo

class esmvalcore.cmor.table.InfoBase(default, alt_names, strict)

Bases: object

Base class for all table info classes.

This uses CMOR 3 json format

Parameters

- **default** (*object*) Default table to look variables on if not found
- alt_names (list [list [str]]) List of known alternative names for variables
- **strict** (bool) If False, will look for a variable in other tables if it can not be found in the requested one

Methods:

```
get_table(table)Search and return the table info.get_variable(table_name, short_name[, de-<br/>rived])Search and return the variable info.
```

get_table(table)

Search and return the table info.

Parameters table (basestring) - Table name

Returns Return the TableInfo object for the requested table if found, returns None if not

Return type TableInfo

get_variable (*table_name*, *short_name*, *derived=False*) Search and return the variable info.

Parameters

- table_name (basestring) Table name
- **short_name** (*basestring*) Variable's short name
- **derived** (*bool*, *optional*) Variable is derived. Info retrieval for derived variables always look on the default tables if variable is not find in the requested table

Returns Return the VariableInfo object for the requested variable if found, returns None if not

Return type VariableInfo

class esmvalcore.cmor.table.JsonInfo

Bases: object

Base class for the info classes.

Provides common utility methods to read json variables

```
class esmvalcore.cmor.table.TableInfo(*args, **kwargs)
```

Bases: dict

Container class for storing a CMOR table.

Methods:

clear()	
сору()	
<pre>fromkeys([value])</pre>	Create a new dictionary with keys from iterable and values set to value.
get(key[, default])	Return the value for key if key is in the dictionary, else default.
items()	
keys()	
pop(k[,d])	If key is not found, d is returned if given, otherwise KeyError is raised
popitem()	2-tuple; but raise KeyError if D is empty.
<pre>setdefault(key[, default])</pre>	Insert key with a value of default if key is not in the dictionary.
update([E,]**F)	If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

	Table 18 – continued from previous page
ralue	e <i>s</i> ()
clea	$ar() \rightarrow None.$ Remove all items from D.
сору	$q() \rightarrow a \text{ shallow copy of } D$
	hkeys (<i>value=None</i> , /) Create a new dictionary with keys from iterable and values set to value.
-	(<i>key</i> , <i>default=None</i> , /) Return the value for key if key is in the dictionary, else default.
item	ns () \rightarrow a set-like object providing a view on D's items
keys	s () \rightarrow a set-like object providing a view on D's keys
	$(k[, d]) \rightarrow v$, remove specified key and return the corresponding value. If key is not found, d is returned if given, otherwise KeyError is raised
	tem () \rightarrow (k, v), remove and return some (key, value) pair as a 2-tuple; but raise KeyError if D is empty.
	default (<i>key</i> , <i>default=None</i> , /) Insert key with a value of default if key is not in the dictionary.
	Return the value for key if key is in the dictionary, else default.
_	ate ($[E]$, ** F) \rightarrow None. Update D from dict/iterable E and F. If E is present and has a .keys() method, then does: for k in E: D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]
valu	des () \rightarrow an object providing a view on D's values

class esmvalcore.cmor.table.VariableInfo(table_type, short_name) Bases: esmvalcore.cmor.table.JsonInfo

Class to read and store variable information.

Attributes:

coordinates	Coordinates
dimensions	List of dimensions
frequency	Data frequency
long_name	Long name
modeling_realm	Modeling realm
positive	Increasing direction
short_name	Short name
standard_name	Standard name
units	Data units
valid_max	Maximum admitted value
valid_min	Minimum admitted value

Methods:

copy()	Return a shallow copy of VariableInfo.
<pre>read_json(json_data, default_freq)</pre>	Read variable information from json.

coordinates

Coordinates

This is a dict with the names of the dimensions as keys and CoordinateInfo objects as values.

copy()

Return a shallow copy of VariableInfo.

Returns Shallow copy of this object

Return type VariableInfo

dimensions

List of dimensions

frequency Data frequency

long_name

Long name

modeling_realm Modeling realm

positive

Increasing direction

read_json (json_data, default_freq)
 Read variable information from json.

Non-present options will be set to empty

Parameters

- **json_data** (*dict*) dictionary created by the json reader containing variable information
- default_freq (str) Default frequency to use if it is not defined at variable level

short_name

Short name

standard_name

Standard name

units

Data units

valid_max

Maximum admitted value

valid_min

Minimum admitted value

esmvalcore.cmor.table.get_var_info(project, mip, short_name)

Get variable information.

Parameters

- **project** (*str*) Dataset's project.
- mip (*str*) Variable's cmor table.
- **short_name** (*str*) Variable's short name.

Parameters cfg_developer (dict of str) - Parsed config-developer file

CHAPTER

TWENTYONE

PREPROCESSOR FUNCTIONS

By default, preprocessor functions are applied in the order in which they are listed here.

Preprocessor module.

Functions:

<pre>amplitude(cube, coords)</pre>	Calculate amplitude of cycles by aggregating over coor- dinates.		
annual_statistics(cube[, operator])	Compute annual statistics.		
anomalies(cube, period[, reference, standardize])	Compute anomalies using a mean with the specified granularity.		
<pre>area_statistics(cube, operator[, fx_variables])</pre>	Apply a statistical operator in the horizontal direction.		
<pre>cleanup(files[, remove])</pre>	Clean up after running the preprocessor.		
<pre>climate_statistics(cube[, operator, period])</pre>	Compute climate statistics with the specified granular- ity.		
<pre>clip(cube[, minimum, maximum])</pre>	Clip values at a specified minimum and/or maximum value		
<pre>cmor_check_data(cube, cmor_table, mip,)</pre>	Check if data conforms to variable's CMOR definiton.		
<pre>cmor_check_metadata(cube, cmor_table, mip,</pre>	Check if metadata conforms to variable's CMOR defini-		
)	ton.		
concatenate(cubes)	Concatenate all cubes after fixing metadata.		
convert_units(cube, units)	Convert the units of a cube to new ones.		
daily_statistics(cube[, operator])	Compute daily statistics.		
<pre>decadal_statistics(cube[, operator])</pre>	Compute decadal statistics.		
depth_integration(cube)	Determine the total sum over the vertical component.		
derive(cubes, short_name, long_name, units)	Derive variable.		
<pre>detrend(cube[, dimension, method])</pre>	Detrend data along a given dimension.		
download(files, dest_folder)	Download files that are not available locally		
<pre>extract_levels(cube, levels, scheme[,])</pre>	Perform vertical interpolation.		
<pre>extract_month(cube, month)</pre>	Slice cube to get only the data belonging to a specific month.		
<pre>extract_named_regions(cube, regions)</pre>	Extract a specific named region.		
<pre>extract_point(cube, latitude, longitude, scheme)</pre>	Extract a point, with interpolation		
<pre>extract_region(cube, start_longitude,)</pre>	Extract a region from a cube.		
extract_season(cube, season)	Slice cube to get only the data belonging to a specific season.		
<pre>extract_shape(cube, shapefile[, method,])</pre>	Extract a region defined by a shapefile.		
<pre>extract_time(cube, start_year, start_month,)</pre>	Extract a time range from a cube.		
<pre>extract_trajectory(cube, latitudes, longitudes)</pre>	Extract data along a trajectory.		

continues on next page

	E traditional la constant la traditional la constant la constant la constant la constant la constant la constant		
<pre>extract_transect(cube[, latitude, longitude])</pre>	Extract data along a line of constant latitude or longi-		
	tude.		
<pre>extract_volume(cube, z_min, z_max)</pre>	Subset a cube based on a range of values in the z-		
	coordinate.		
<pre>fix_data(cube, short_name, project, dataset, mip)</pre>	Fix cube data if fixes add present and check it anyway.		
<pre>fix_file(file, short_name, project, dataset,)</pre>	Fix files before ESMValTool can load them.		
<pre>fix_metadata(cubes, short_name, project,)</pre>	Fix cube metadata if fixes are required and check it any-		
	way.		
load(file[, callback])	Load iris cubes from files.		
<pre>mask_above_threshold(cube, threshold)</pre>	Mask above a specific threshold value.		
<pre>mask_below_threshold(cube, threshold)</pre>	Mask below a specific threshold value.		
<pre>mask_fillvalues(products, threshold_fraction)</pre>	Compute and apply a multi-dataset fillvalues mask.		
<pre>mask_glaciated(cube, mask_out)</pre>	Mask out glaciated areas.		
<pre>mask_inside_range(cube, minimum, maximum)</pre>	Mask inside a specific threshold range.		
<pre>mask_landsea(cube, fx_variables, mask_out[,])</pre>	Mask out either land mass or sea (oceans, seas and		
	lakes).		
1 7 1 1 $(1$ 1 1 $(2$ 1 1 $(3$ 1 1 $(3$ 1 1 $(3$ 1 1 $(3$ 1 1 $(3$ 1 $1)$ (4)			
<pre>mask_landseaice(cube, fx_variables, mask_out)</pre>	Mask out either landsea (combined) or ice.		
mask_landsealce(cube, rx_variables, mask_out) mask_outside_range(cube, minimum, maximum)	Mask out either landsea (combined) or ice. Mask outside a specific threshold range.		
	· · · · · ·		
<pre>mask_outside_range(cube, minimum, maximum)</pre>	Mask outside a specific threshold range.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator)</pre>	Mask outside a specific threshold range. Compute meridional statistics.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator])</pre>	Mask outside a specific threshold range. Compute meridional statistics. Compute monthly statistics.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,)</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,])</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,]) regrid_time(cube, frequency)</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.Align time axis for cubes so they can be subtracted.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,]) regrid_time(cube, frequency) save(cubes, filename[, optimize_access,])</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.Align time axis for cubes so they can be subtracted.Save iris cubes to file.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,]) regrid_time(cube, frequency) save(cubes, filename[, optimize_access,]) seasonal_statistics(cube[, operator])</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.Align time axis for cubes so they can be subtracted.Save iris cubes to file.Compute seasonal statistics.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,]) regrid_time(cube, frequency) save(cubes, filename[, optimize_access,]) seasonal_statistics(cube[, operator]) timeseries_filter(cube, window, span[,])</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.Align time axis for cubes so they can be subtracted.Save iris cubes to file.Compute seasonal statistics.Apply a timeseries filter.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,]) regrid_time(cube, frequency) save(cubes, filename[, optimize_access,]) seasonal_statistics(cube[, operator]) timeseries_filter(cube, window, span[,]) volume_statistics(cube, operator[,</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.Align time axis for cubes so they can be subtracted.Save iris cubes to file.Compute seasonal statistics.Apply a timeseries filter.		
<pre>mask_outside_range(cube, minimum, maximum) meridional_statistics(cube, operator) monthly_statistics(cube[, operator]) multi_model_statistics(products, span,) regrid(cube, target_grid, scheme[,]) regrid_time(cube, frequency) save(cubes, filename[, optimize_access,]) seasonal_statistics(cube[, operator]) timeseries_filter(cube, window, span[,]) volume_statistics(cube, operator[, fx_variables])</pre>	Mask outside a specific threshold range.Compute meridional statistics.Compute monthly statistics.Compute multi-model statistics.Perform horizontal regridding.Align time axis for cubes so they can be subtracted.Save iris cubes to file.Compute seasonal statistics.Apply a timeseries filter.Apply a statistical operation over a volume.		

		•		
Table 1 –	continued	trom	previous	page

esmvalcore.preprocessor.amplitude(cube, coords)

Calculate amplitude of cycles by aggregating over coordinates.

Note: The amplitude is calculated as *peak-to-peak* amplitude (difference between maximum and minimum value of the signal). Other amplitude types are currently not supported.

Parameters

- cube (iris.cube.Cube) Input data.
- **coords** (*str or list of str*) Coordinates over which is aggregated. For example, use 'year' to extract the annual cycle amplitude for each year in the data or ['day_of_year', 'year'] to extract the diurnal cycle amplitude for each individual day in the data. If the coordinates are not found in cube, try to add it via iris.coord_categorisation (at the moment, this only works for the temporal coordinates day_of_month, day_of_year, hour, month, month_fullname, month_number, season, season_number, season_year, weekday, weekday_fullname, weekday_number or year.

Returns Amplitudes.

Return type iris.cube.Cube

Raises iris.exceptions.CoordinateNotFoundError – A coordinate is not found in cube and cannot be added via iris.coord_categorisation.

esmvalcore.preprocessor.annual_statistics(cube, operator='mean')

Compute annual statistics.

Note that this function does not weight the annual mean if uneven time periods are present. Ie, all data inside the year are treated equally.

Parameters

- cube (iris.cube.Cube) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'max', 'rms'

Returns Annual statistics cube

Return type iris.cube.Cube

```
esmvalcore.preprocessor.anomalies (cube, period, reference=None, standardize=False)
Compute anomalies using a mean with the specified granularity.
```

Computes anomalies based on daily, monthly, seasonal or yearly means for the full available period

Parameters

- cube (iris.cube.Cube) input cube.
- **period** (*str*) Period to compute the statistic over. Available periods: 'full', 'season', 'seasonal', 'monthly', 'month', 'mon', 'daily', 'day'
- **reference** (list int, optional, default: None) Period of time to use a reference, as needed for the 'extract_time' preprocessor function If None, all available data is used as a reference
- **standardize** (bool, optional) If True standardized anomalies are calculated

Returns Anomalies cube

Return type iris.cube.Cube

esmvalcore.preprocessor.**area_statistics** (*cube*, *operator*, *fx_variables=None*) Apply a statistical operator in the horizontal direction.

The average in the horizontal direction. We assume that the horizontal directions are ['longitude', 'latutude'].

This function can be used to apply several different operations in the horizontal plane: mean, standard deviation, median variance, minimum and maximum. These options are specified using the *operator* argument and the following key word arguments:

mean	Area weighted mean.
median	Median (not area weighted)
std_dev	Standard Deviation (not area weighted)
sum	Area weighted sum.
variance	Variance (not area weighted)
min:	Minimum value
max	Maximum value
rms	Area weighted root mean square.

Parameters

• cube (iris.cube.Cube) - Input cube.

- **operator** (*str*) The operation, options: mean, median, min, max, std_dev, sum, variance, rms.
- **fx_variables** (*dict*) dictionary of field:filename for the fx_variables

Returns collapsed cube.

Return type iris.cube.Cube

Raises

- **iris.exceptions.CoordinateMultiDimError** Exception for latitude axis with dim > 2.
- ValueError if input data cube has different shape than grid area weights

esmvalcore.preprocessor.cleanup(files, remove=None)

Clean up after running the preprocessor.

esmvalcore.preprocessor.climate_statistics (*cube*, *operator='mean'*, *period='full'*) Compute climate statistics with the specified granularity.

Computes statistics for the whole dataset. It is possible to get them for the full period or with the data grouped by day, month or season

Parameters

- cube (iris.cube.Cube) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'
- **period** (*str*, *optional*) Period to compute the statistic over. Available periods: 'full', 'season', 'seasonal', 'monthly', 'month', 'mon', 'daily', 'day'

Returns Monthly statistics cube

Return type iris.cube.Cube

esmvalcore.preprocessor.clip(cube, minimum=None, maximum=None)

Clip values at a specified minimum and/or maximum value

Values lower than minimum are set to minimum and values higher than maximum are set to maximum.

Parameters

- cube (*iris.cube.Cube*) iris cube to be clipped
- **minimum** (*float*) lower threshold to be applied on input cube data.
- **maximum** (float) upper threshold to be applied on input cube data.

Returns clipped cube.

Return type iris.cube.Cube

Check if data conforms to variable's CMOR definiton.

The checks performed at this step require the data in memory.

Parameters

- **cube** (*iris.cube.Cube*) Data cube to check.
- **cmor_table** (*basestring*) **CMOR** definitions to use.

- **mip** Variable's mip.
- **short_name** (*basestring*) Variable's short name
- frequency (basestring) Data frequency
- check_level (CheckLevels) Level of strictness of the checks.

```
esmvalcore.preprocessor.cmor_check_metadata(cube, cmor_table, mip,
short_name, frequency,
check_level=<CheckLevels.DEFAULT:</pre>
```

3>) Check if metadata conforms to variable's CMOR definiton.

None of the checks at this step will force the cube to load the data.

Parameters

- **cube** (*iris.cube.Cube*) Data cube to check.
- **cmor_table** (*basestring*) **CMOR** definitions to use.
- **mip** Variable's mip.
- **short_name** (*basestring*) Variable's short name.
- **frequency** (basestring) Data frequency.
- check_level (CheckLevels) Level of strictness of the checks.

esmvalcore.preprocessor.concatenate(cubes)

Concatenate all cubes after fixing metadata.

esmvalcore.preprocessor.convert_units(cube, units)

Convert the units of a cube to new ones.

This converts units of a cube.

Parameters

- cube (iris.cube.Cube) input cube
- units (*str*) new units in udunits form

Returns converted cube.

Return type iris.cube.Cube

esmvalcore.preprocessor.daily_statistics(cube, operator='mean')

Compute daily statistics.

Chunks time in daily periods and computes statistics over them;

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'max', 'rms'

Returns Daily statistics cube

Return type iris.cube.Cube

```
esmvalcore.preprocessor.decadal_statistics (cube, operator='mean')
Compute decadal statistics.
```

Note that this function does not weight the decadal mean if uneven time periods are present. Ie, all data inside the decade are treated equally.

Parameters

- cube (iris.cube.Cube) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'

Returns Decadal statistics cube

Return type iris.cube.Cube

esmvalcore.preprocessor.**depth_integration** (*cube*) Determine the total sum over the vertical component.

Requires a 3D cube. The z-coordinate integration is calculated by taking the sum in the z direction of the cell contents multiplied by the cell thickness.

Parameters cube (iris.cube.Cube) - input cube.

Returns collapsed cube.

Return type iris.cube.Cube

esmvalcore.preprocessor.derive (cubes, short_name, long_name, units, standard_name=None)
Derive variable.

Parameters

- **cubes** (*iris.cube.CubeList*) Includes all the needed variables for derivation defined in get_required().
- short_name (str) short_name
- long_name (str) long_name
- units (str) units
- standard_name (str, optional) standard_name

Returns The new derived variable.

Return type iris.cube.Cube

esmvalcore.preprocessor.detrend (*cube*, *dimension='time'*, *method='linear'*) Detrend data along a given dimension.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **dimension** (*str*) Dimension to detrend
- **method** (*str*) Method to detrend. Available: linear, constant. See documentation of 'scipy.signal.detrend' for details

Returns Detrended cube

Return type iris.cube.Cube

esmvalcore.preprocessor.download (*files*, *dest_folder*) Download files that are not available locally

esmvalcore.preprocessor.extract_levels(cube, levels, scheme, coordinate=None)

Perform vertical interpolation.

Parameters

• **cube** (*cube*) – The source cube to be vertically interpolated.

- **levels** (*array*) One or more target levels for the vertical interpolation. Assumed to be in the same S.I. units of the source cube vertical dimension coordinate.
- **scheme** (*str*) The vertical interpolation scheme to use. Choose from 'linear', 'nearest', 'nearest_horizontal_extrapolate_vertical', 'linear_horizontal_extrapolate_vertical'.
- coordinate (optional str) The coordinate to interpolate

Returns

Return type cube

See also:

regrid Perform horizontal regridding.

esmvalcore.preprocessor.extract_month(cube, month)

Slice cube to get only the data belonging to a specific month.

Parameters

- **cube** (*iris.cube.Cube*) Original data
- month (int) Month to extract as a number from 1 to 12

Returns data cube for specified month.

Return type iris.cube.Cube

```
esmvalcore.preprocessor.extract_named_regions(cube, regions)
```

Extract a specific named region.

The region coordinate exist in certain CMIP datasets. This preprocessor allows a specific named regions to be extracted.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **regions** (*str*, *list*) A region or list of regions to extract.

Returns collapsed cube.

Return type iris.cube.Cube

Raises

- ValueError regions is not list or tuple or set.
- **ValueError** region not included in cube.

esmvalcore.preprocessor.extract_point (cube, latitude, longitude, scheme)

Extract a point, with interpolation

Extracts a single latitude/longitude point from a cube, according to the interpolation scheme scheme.

Multiple points can also be extracted, by supplying an array of latitude and/or longitude coordinates. The resulting point cube will match the respective latitude and longitude coordinate to those of the input coordinates. If the input coordinate is a scalar, the dimension will be missing in the output cube (that is, it will be a scalar).

Parameters

- **cube** (*cube*) The source cube to extract a point from.
- latitude (float, or array of float) The latitude and longitude of the point.

- **longitude** (*float*, *or array of float*) The latitude and longitude of the point.
- **scheme** (*str*) The interpolation scheme. 'linear' or 'nearest'. No default.

Returns

- *Returns a cube with the extracted point(s), and with adjusted*
- latitude and longitude coordinates (see above).

Examples

With a cube that has the coordinates

- latitude: [1, 2, 3, 4]
- longitude: [1, 2, 3, 4]
- data values: [[[1, 2, 3, 4], [5, 6, ...], [...], [...], ...]]]

```
>>> point = extract_point(cube, 2.5, 2.5, 'linear')
>>> point.data
array([ 8.5, 24.5, 40.5, 56.5])
```

Extraction of multiple points at once, with a nearest matching scheme. The values for 0.1 will result in masked values, since this lies outside the cube grid.

```
>>> point = extract_point(cube, [1.4, 2.1], [0.1, 1.1],
... 'nearest')
>>> point.data.shape
(4, 2, 2)
>>> # x, y, z indices of masked values
>>> np.where(~point.data.mask)
(array([0, 0, 1, 1, 2, 2, 3, 3]), array([0, 1, 0, 1, 0, 1, 0, 1]),
array([1, 1, 1, 1, 1, 1]))
>>> point.data[~point.data.mask].data
array([ 1, 5, 17, 21, 33, 37, 49, 53])
```

Extract a region from a cube.

Function that subsets a cube on a box (start_longitude, end_longitude, start_latitude, end_latitude) This function is a restriction of masked_cube_lonlat().

Parameters

- cube (iris.cube.Cube) input data cube.
- **start_longitude** (*float*) Western boundary longitude.
- end_longitude (float) Eastern boundary longitude.
- **start_latitude** (*float*) Southern Boundary latitude.
- end_latitude (float) Northern Boundary Latitude.

Returns smaller cube.

Return type iris.cube.Cube

esmvalcore.preprocessor.extract_season(cube, season)

Slice cube to get only the data belonging to a specific season.

Parameters

- cube (iris.cube.Cube) Original data
- season (*str*) Season to extract. Available: DJF, MAM, JJA, SON

Returns data cube for specified season.

Return type iris.cube.Cube

esmvalcore.preprocessor.extract_shape(cube, shapefile, method='contains', crop=True, decomposed=False)

Extract a region defined by a shapefile.

Note that this function does not work for shapes crossing the prime meridian or poles.

Parameters

- cube (iris.cube.Cube) input cube.
- **shapefile** (*str*) A shapefile defining the region(s) to extract.
- **method** (*str*, *optional*) Select all points contained by the shape or select a single representative point. Choose either 'contains' or 'representative'. If 'contains' is used, but not a single grid point is contained by the shape, a representative point will selected.
- **crop** (*bool*, *optional*) Crop the resulting cube using *extract_region()*. Note that data on irregular grids will not be cropped.
- **decomposed** (*bool*, *optional*) Whether or not to retain the sub shapes of the shapefile in the output. If this is set to True, the output cube has a dimension for the sub shapes.

Returns Cube containing the extracted region.

Return type iris.cube.Cube

See also:

extract_region Extract a region from a cube.

```
esmvalcore.preprocessor.extract_time(cube, start_year, start_month, start_day, end_year,
```

end_month, end_day)

Extract a time range from a cube.

Given a time range passed in as a series of years, months and days, it returns a time-extracted cube with data only within the specified time range.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **start_year** (*int*) start year
- start_month(int) start month
- **start_day** (*int*) **start** day
- end_year (int) end year
- **end_month** (*int*) end month
- end_day (int) end day

Returns Sliced cube.

Return type iris.cube.Cube

Raises ValueError – if time ranges are outside the cube time limits

esmvalcore.preprocessor.extract_trajectory (*cube*, *latitudes*, *longitudes*, *number_points=2*) Extract data along a trajectory.

latitudes and longitudes are the pairs of coordinates for two points. number_points is the number of points between the two points.

This version uses the expensive interpolate method, but it may be necceasiry for irregular grids.

If only two latitude and longitude coordinates are given, extract_trajectory will produce a cube will extrapolate along a line between those two points, and will add *number_points* points between the two corners.

If more than two points are provided, then extract_trajectory will produce a cube which has extrapolated the data of the cube to those points, and *number_points* is not needed.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **latitudes** (*list*) list of latitude coordinates (floats).
- longitudes (list) list of longitude coordinates (floats).
- number_points (*int*) number of points to extrapolate (optional).

Returns collapsed cube.

Return type iris.cube.Cube

Raises ValueError – if latitude and longitude have different dimensions.

esmvalcore.preprocessor.extract_transect (cube, latitude=None, longitude=None)

Extract data along a line of constant latitude or longitude.

Both arguments, latitude and longitude, are treated identically. Either argument can be a single float, or a pair of floats, or can be left empty. The single float indicates the latitude or longitude along which the transect should be extracted. A pair of floats indicate the range that the transect should be extracted along the secondairy axis.

For instance 'extract_transect(cube, longitude=-28)' will produce a transect along 28 West.

Also, '*extract_transect(cube, longitude=-28, latitude=[-50, 50])*' will produce a transect along 28 West between 50 south and 50 North.

This function is not yet implemented for irregular arrays - instead try the extract_trajectory function, but note that it is currently very slow. Alternatively, use the regrid preprocessor to regrid along a regular grid and then extract the transect.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **latitude** (*None*, float or [float, float], optional) transect latitude or range.
- longitude (None, float or [float, float], optional) transect longitude or range.

Returns collapsed cube.

Return type iris.cube.Cube

Raises

- **ValueError** slice extraction not implemented for irregular grids.
- **ValueError** latitude and longitude are both floats or lists; not allowed to slice on both axes at the same time.

esmvalcore.preprocessor.extract_volume(cube, z_min, z_max)

Subset a cube based on a range of values in the z-coordinate.

Function that subsets a cube on a box (z_min, z_max) This function is a restriction of masked_cube_lonlat(); Note that this requires the requested z-coordinate range to be the same sign as the iris cube. ie, if the cube has z-coordinate as negative, then z_min and z_max need to be negative numbers.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **z_min** (*float*) minimum depth to extract.
- **z_max** (*float*) maximum depth to extract.

Returns z-coord extracted cube.

Return type iris.cube.Cube

Fix cube data if fixes add present and check it anyway.

This method assumes that metadata is already fixed and checked.

This method collects all the relevant fixes for a given variable, applies them and checks resulting cube (or the original if no fixes were needed) metadata to ensure that it complies with the standards of its project CMOR tables.

Parameters

- cube (iris.cube.Cube) Cube to fix
- **short_name** (*str*) Variable's short name
- project (str)-
- dataset (str)-
- mip (str) Variable's MIP
- **frequency** (*str*, *optional*) Variable's data frequency, if available
- check_level (CheckLevels) Level of strictness of the checks. Set to default.

Returns Fixed and checked cube

Return type iris.cube.Cube

Raises CMORCheckError – If the checker detects errors in the data that it can not fix.

esmvalcore.preprocessor.fix_file (*file, short_name, project, dataset, mip, output_dir*) Fix files before ESMValTool can load them.

This fixes are only for issues that prevent iris from loading the cube or that cannot be fixed after the cube is loaded.

Original files are not overwritten.

Parameters

- **file** (*str*) Path to the original file
- **short_name** (*str*) Variable's short name

- project (str)-
- dataset (str)-
- **output_dir** (*str*) Output directory for fixed files

Returns Path to the fixed file

Return type str

```
esmvalcore.preprocessor.fix_metadata(cubes, short_name, project, dataset, mip, fre-
quency=None, check_level=<CheckLevels.DEFAULT:
3>)
```

Fix cube metadata if fixes are required and check it anyway.

This method collects all the relevant fixes for a given variable, applies them and checks the resulting cube (or the original if no fixes were needed) metadata to ensure that it complies with the standards of its project CMOR tables.

Parameters

- cubes (iris.cube.CubeList) Cubes to fix
- **short_name** (*str*) Variable's short name
- project (str)-
- dataset (str) -
- mip (str) Variable's MIP
- frequency (str, optional) Variable's data frequency, if available
- check_level (CheckLevels) Level of strictness of the checks. Set to default.

Returns Fixed and checked cube

Return type iris.cube.Cube

Raises CMORCheckError – If the checker detects errors in the metadata that it can not fix.

esmvalcore.preprocessor.load(file, callback=None)

Load iris cubes from files.

```
esmvalcore.preprocessor.mask_above_threshold(cube, threshold)
```

Mask above a specific threshold value.

Takes a value 'threshold' and masks off anything that is above it in the cube data. Values equal to the threshold are not masked.

Parameters

- cube (iris.cube.Cube) iris cube to be thresholded.
- threshold (float) threshold to be applied on input cube data.

Returns thresholded cube.

Return type iris.cube.Cube

```
esmvalcore.preprocessor.mask_below_threshold(cube, threshold)
```

Mask below a specific threshold value.

Takes a value 'threshold' and masks off anything that is below it in the cube data. Values equal to the threshold are not masked.

Parameters

• **cube** (*iris.cube.Cube*) – iris cube to be thresholded

• **threshold** (*float*) – threshold to be applied on input cube data.

Returns thresholded cube.

Return type iris.cube.Cube

esmvalcore.preprocessor.mask_fillvalues (products, threshold_fraction, min_value=None,

time_window=1) Compute and apply a multi-dataset fillvalues mask.

Construct the mask that fills a certain time window with missing values if the number of values in that specific window is less than a given fractional threshold. This function is the extension of _get_fillvalues_mask and performs the combination of missing values masks from each model (of multimodels) into a single fillvalues mask to be applied to each model.

Parameters

- products (*iris.cube.Cube*) data products to be masked.
- **threshold_fraction** (*float*) fractional threshold to be used as argument for Aggregator. Must be between 0 and 1.
- **min_value** (*float*) minimum value threshold; default None If default, no thresholding applied so the full mask will be selected.
- time_window (float) time window to compute missing data counts; default set to 1.

Returns Masked iris cubes.

Return type iris.cube.Cube

Raises NotImplementedError – Implementation missing for data with higher dimensionality than 4.

esmvalcore.preprocessor.mask_glaciated(cube, mask_out)

Mask out glaciated areas.

It applies a Natural Earth mask. Note that for computational reasons only the 10 largest polygons are used for masking.

Parameters

- cube (iris.cube.Cube) data cube to be masked.
- mask_out (str) "glaciated" to mask out glaciated areas

Returns Returns the masked iris cube.

Return type iris.cube.Cube

Raises ValueError – Error raised if masking on irregular grids is attempted or if mask_out has a wrong value.

esmvalcore.preprocessor.mask_inside_range(cube, minimum, maximum)

Mask inside a specific threshold range.

Takes a MINIMUM and a MAXIMUM value for the range, and masks off anything that's between the two in the cube data.

Parameters

- cube (iris.cube.Cube) iris cube to be thresholded
- **minimum** (*float*) lower threshold to be applied on input cube data.
- **maximum** (*float*) upper threshold to be applied on input cube data.

Returns thresholded cube.

Return type iris.cube.Cube

esmvalcore.preprocessor.mask_landsea(cube, fx_variables, mask_out, always_use_ne_mask=False)

Mask out either land mass or sea (oceans, seas and lakes).

It uses dedicated fx files (sftlf or sftof) or, in their absence, it applies a Natural Earth mask (land or ocean contours). Note that the Natural Earth masks have different resolutions: 10m for land, and 50m for seas; these are more than enough for ESMValTool puppose.

Parameters

- **cube** (*iris.cube.Cube*) data cube to be masked.
- **fx_variables** (*dict*) dict: keys: fx variables, values: full paths to fx files.
- **mask_out** (*str*) either "land" to mask out land mass or "sea" to mask out seas.
- always_use_ne_mask (bool, optional (default: False)) always apply Natural Earths mask, regardless if fx files are available or not.

Returns Returns the masked iris cube.

Return type iris.cube.Cube

Raises ValueError – Error raised if masking on irregular grids is attempted. Irregular grids are not currently supported for masking with Natural Earth shapefile masks.

esmvalcore.preprocessor.mask_landseaice(*cube*, *fx_variables*, *mask_out*) Mask out either landsea (combined) or ice.

Mask out either fandsea (combined) of ice.

Function that masks out either landsea (land and seas) or ice (Antarctica and Greenland and some wee glaciers). It uses dedicated fx files (sftgif).

Parameters

- **cube** (*iris.cube.Cube*) data cube to be masked.
- **fx_variables** (*dict*) dict: keys: fx variables, values: full paths to fx files.
- **mask_out** (*str*) either "landsea" to mask out landsea or "ice" to mask out ice.

Returns Returns the masked iris cube with either land or ice masked out.

Return type iris.cube.Cube

Raises

- **ValueError** Error raised if fx mask and data have different dimensions.
- **ValueError** Error raised if fx files list is empty.

esmvalcore.preprocessor.mask_outside_range(cube, minimum, maximum)

Mask outside a specific threshold range.

Takes a MINIMUM and a MAXIMUM value for the range, and masks off anything that's outside the two in the cube data.

Parameters

- **cube** (*iris.cube.Cube*) iris cube to be thresholded
- **minimum** (float) lower threshold to be applied on input cube data.
- **maximum** (float) upper threshold to be applied on input cube data.

Returns thresholded cube.

Return type iris.cube.Cube

esmvalcore.preprocessor.meridional_statistics(cube, operator)

Compute meridional statistics.

Parameters

- cube (iris.cube.Cube) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'max', 'rms'.

Returns Meridional statistics cube.

Return type iris.cube.Cube

Raises ValueError – Error raised if computation on irregular grids is attempted. Zonal statistics not yet implemented for irregular grids.

```
esmvalcore.preprocessor.monthly_statistics(cube, operator='mean')
```

Compute monthly statistics.

Chunks time in monthly periods and computes statistics over them;

Parameters

- cube (iris.cube.Cube) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'

Returns Monthly statistics cube

Return type iris.cube.Cube

```
esmvalcore.preprocessor.multi_model_statistics (products, span, statistics, out-
put_products=None)
```

Compute multi-model statistics.

Multimodel statistics computed along the time axis. Can be computed across a common overlap in time (set span: overlap) or across the full length in time of each model (set span: full). Restrictive computation is also available by excluding any set of models that the user will not want to include in the statistics (set exclude: [excluded models list]).

Restrictions needed by the input data: - model datasets must have consistent shapes, - higher dimensional data is not supported (ie dims higher than four: time, vertical axis, two horizontal axes).

Parameters

- **products** (*list*) list of data products or cubes to be used in multimodel stat computation; cube attribute of product is the data cube for computing the stats.
- **span** (*str*) overlap or full; if overlap, statisticss are computed on common time- span; if full, statistics are computed on full time spans, ignoring missing data.
- **output_products** (*dict*) dictionary of output products.
- **statistics** (*str*) statistical measure to be computed. Available options: mean, median, max, min, std, or pXX.YY (for percentile XX.YY; decimal part optional).

Returns list of data products or cubes containing the multimodel stats computed.

Return type list

Raises ValueError – If span is neither overlap nor full.

esmvalcore.preprocessor.regrid(cube, target_grid, scheme, lat_offset=True, lon_offset=True)
Perform horizontal regridding.

Parameters

- **cube** (*cube*) The source cube to be regridded.
- target_grid (*cube or str*) The cube that specifies the target or reference grid for the regridding operation. Alternatively, a string cell specification may be provided, of the form 'MxN', which specifies the extent of the cell, longitude by latitude (degrees) for a global, regular target grid.
- **scheme** (*str*) The regridding scheme to perform, choose from 'linear', 'linear_extrapolate', 'nearest', 'area_weighted', 'unstructured_nearest'.
- **lat_offset** (*bool*) Offset the grid centers of the latitude coordinate w.r.t. the pole by half a grid step. This argument is ignored if *target_grid* is a cube or file.
- **lon_offset** (*bool*) Offset the grid centers of the longitude coordinate w.r.t. Greenwich meridian by half a grid step. This argument is ignored if *target_grid* is a cube or file.

Returns

Return type cube

See also:

extract_levels Perform vertical regridding.

```
esmvalcore.preprocessor.regrid_time(cube, frequency)
```

Align time axis for cubes so they can be subtracted.

Operations on time units, time points and auxiliary coordinates so that any cube from cubes can be subtracted from any other cube from cubes. Currently this function supports yearly (frequency=yr), monthly (frequency=mon), daily (frequency=day), 6-hourly (frequency=6hr), 3-hourly (frequency=3hr) and hourly (frequency=1hr) data time frequencies.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **frequency** (*str*) data frequency: mon, day, 1hr, 3hr or 6hr

Returns cube with converted time axis and units.

Return type iris.cube.Cube

Save iris cubes to file.

Parameters

- cubes (iterable of iris.cube.Cube) Data cubes to be saved
- **filename** (*str*) Name of target file
- **optimize_access** (*str*) Set internal NetCDF chunking to favour a reading scheme

Values can be map or timeseries, which improve performance when reading the file one map or time series at a time. Users can also provide a coordinate or a list of coordinates. In that case the better performance will be avhieved by loading all the values in that coordinate at a time

• **compress** (bool, optional) – Use NetCDF internal compression.

Returns filename

Return type str

esmvalcore.preprocessor.seasonal_statistics (*cube*, *operator='mean'*) Compute seasonal statistics.

Chunks time in 3-month periods and computes statistics over them;

Parameters

- cube (iris.cube.Cube) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'

ter stats='sum')

Returns Seasonal statistic cube

Return type iris.cube.Cube

esmvalcore.preprocessor.timeseries_filter(cube, window, span, filter_type='lowpass', fil-

Apply a timeseries filter.

Method borrowed from iris example

Apply each filter using the rolling_window method used with the weights keyword argument. A weighted sum is required because the magnitude of the weights are just as important as their relative sizes.

See also the iris rolling window

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- window (*int*) The length of the filter window (in units of cube time coordinate).
- **span** (*int*) Number of months/days (depending on data frequency) on which weights should be computed e.g. 2-yearly: span = 24 (2 x 12 months). Span should have same units as cube time coordinate.
- **filter_type** (*str*, *optional*) Type of filter to be applied; default 'lowpass'. Available types: 'lowpass'.
- **filter_stats** (*str*, *optional*) Type of statistic to aggregate on the rolling window; default 'sum'. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'

Returns cube time-filtered using 'rolling_window'.

Return type iris.cube.Cube

Raises

- **iris.exceptions.CoordinateNotFoundError**: Cube does not have time coordinate.
- **NotImplementedError**: If filter_type is not implemented.

esmvalcore.preprocessor.volume_statistics (*cube*, *operator*, *fx_variables=None*) Apply a statistical operation over a volume.

The volume average is weighted according to the cell volume. Cell volume is calculated from iris's cartography tool multiplied by the cell thickness.

Parameters

- cube (iris.cube.Cube) Input cube.
- **operator** (*str*) The operation to apply to the cube, options are: 'mean'.
- **fx_variables** (*dict*) dictionary of field:filename for the fx_variables

Returns collapsed cube.

Return type iris.cube.Cube

Raises ValueError – if input cube shape differs from grid volume cube shape.

esmvalcore.preprocessor.weighting_landsea_fraction(cube,fx_variables, area_type)

Weight fields using land or sea fraction.

This preprocessor function weights a field with its corresponding land or sea area fraction (value between 0 and 1). The application of this is important for most carbon cycle variables (and other land-surface outputs), which are e.g. reported in units of kgC m-2. This actually refers to 'per square meter of land/sea' and NOT 'per square meter of gridbox'. So in order to integrate these globally or regionally one has to both area-weight the quantity but also weight by the land/sea fraction.

Parameters

- **cube** (*iris.cube.Cube*) Data cube to be weighted.
- **fx_variables** (*dict*) Dictionary holding var_name (keys) and full paths (values) to the fx files as str or empty list (if not available).
- area_type (*str*) Use land ('land') or sea ('sea') fraction for weighting.

Returns Land/sea fraction weighted cube.

Return type iris.cube.Cube

Raises

- **TypeError** area_type is not 'land' or 'sea'.
- **ValueError** Land/sea fraction variables sftlf or sftof not found or shape of them is not broadcastable to cube.

esmvalcore.preprocessor.zonal_statistics(cube, operator)

Compute zonal statistics.

Parameters

- **cube** (*iris.cube.Cube*) input cube.
- **operator** (*str*, *optional*) Select operator to apply. Available operators: 'mean', 'median', 'std_dev', 'sum', 'min', 'max', 'rms'.

Returns Zonal statistics cube.

Return type iris.cube.Cube

Raises ValueError – Error raised if computation on irregular grids is attempted. Zonal statistics not yet implemented for irregular grids.

Part VII

Changelog

CHAPTER

TWENTYTWO

V2.1.0

This release includes

22.1 Bug fixes

- Set unit=1 if anomalies are standardized (#727) bascrezee
- Fix crash for FGOALS-g2 variables without longitude coordinate (#729) Bouwe Andela
- Improve variable alias management (#595) Javier Vegas-Regidor
- Fix area_statistics fx files loading (#798) Javier Vegas-Regidor
- Fix units after derivation (#754) Manuel Schlund

22.2 Documentation

- Update v2.0.0 release notes with final additions (#722) Bouwe Andela
- Update package description in setup.py (#725) Mattia Righi
- Add installation instructions for pip installation (#735) Bouwe Andela
- Improve config-user documentation (#740) Bouwe Andela
- Update the zenodo file with contributors (#807) Valeriu Predoi
- Improve command line run documentation (#721) Javier Vegas-Regidor
- Update the zenodo file with contributors (continued) (#810) Valeriu Predoi

22.3 Improvements

- Reduce size of docker image (#723) Javier Vegas-Regidor
- Add 'test' extra to installation, used by docker development tag (#733) Bouwe Andela
- Correct dockerhub link (#736) Bouwe Andela
- Create action-install-from-pypi.yml (#734) Valeriu Predoi
- Add pre-commit for linting/formatting (#766) Stef Smeets
- Run tests in parallel and when building conda package (#745) Bouwe Andela

- Readable exclude pattern for pre-commit (#770) Stef Smeets
- Github Actions Tests (#732) Valeriu Predoi
- Remove isort setup to fix formatting conflict with yapf (#778) Stef Smeets
- Fix yapf-isort import formatting conflict (Fixes #777) (#784) Stef Smeets
- Sorted output for esmvaltool recipes list (#790) Stef Smeets
- Replace vmprof with vprof (#780) Valeriu Predoi
- Update CMIP6 tables to 6.9.32 (#706) Javier Vegas-Regidor
- Default config-user path now set in config-user read function (#791) Javier Vegas-Regidor
- Add custom variable lweGrace (#692) bascrezee
- Create Github Actions workflow to build and deploy on Test PyPi and PyPi (#820) Valeriu Predoi
- Build and publish the esmvalcore package to conda via Github Actions workflow (#825) Valeriu Predoi

22.4 Fixes for datasets

- Fix cmip6 models (#629) npgillett
- Fix siconca variable in EC-Earth3 and EC-Earth3-Veg models in amip simulation (#702) Evgenia Galytska

22.5 Preprocessor

- Move cmor_check_data to early in preprocessing chain (#743) Bouwe Andela
- Add RMS iris analysis operator to statistics preprocessor functions (#747) Pep Cos
- Add surface chlorophyll concentration as a derived variable (#720) sloosvel
- Use dask to reduce memory consumption of extract_levels for masked data (#776) Valeriu Predoi

CHAPTER TWENTYTHREE

V2.0.0

This release includes

23.1 Bug fixes

- Fixed derivation of co2s (#594) Manuel Schlund
- Padding while cropping needs to stay within sane bounds for shapefiles that span the whole Earth (#626) Valeriu Predoi
- Fix concatenation of a single cube (#655) Bouwe Andela
- Fix mask fx dict handling not to fail if empty list in values (#661) Valeriu Predoi
- Preserve metadata during anomalies computation when using iris cubes difference (#652) Valeriu Predoi
- Avoid crashing when there is directory 'esmvaltool' in the current working directory (#672) Valeriu Predoi
- Solve bug in ACCESS1 dataset fix for calendar. (#671) Peter Kalverla
- Fix the syntax for adding multiple ensemble members from the same dataset (#678) SarahAlidoost
- Fix bug that made preprocessor with fx files fail in rare cases (#670) Manuel Schlund
- Add support for string coordinates (#657) Javier Vegas-Regidor
- Fixed the shape extraction to account for wraparound shapefile coords (#319) Valeriu Predoi
- Fixed bug in time weights calculation (#695) Manuel Schlund
- Fix diagnostic filter (#713) Javier Vegas-Regidor

23.2 Documentation

- Add pandas as a requirement for building the documentation (#607) Bouwe Andela
- Document default order in which preprocessor functions are applied (#633) Bouwe Andela
- Add pointers about data loading and CF standards to documentation (#571) Valeriu Predoi
- Config file populated with site-specific data paths examples (#619) Valeriu Predoi
- Update Codacy badges (#643) Bouwe Andela
- Update copyright info on readthedocs (#668) Bouwe Andela
- Updated references to documentation (now docs.esmvaltool.org) (#675) Axel Lauer

- Add all European grants to Zenodo (#680) Bouwe Andela
- Update Sphinx to v3 or later (#683) Bouwe Andela
- Increase version to 2.0.0 and add release notes (#691) Bouwe Andela
- Update setup.py and README.md for use on PyPI (#693) Bouwe Andela
- Suggested Documentation changes (#690) Steve Smith

23.3 Improvements

- Reduce the size of conda package (#606) Bouwe Andela
- Add a few unit tests for DiagnosticTask (#613) Bouwe Andela
- Make ncl or R tests not fail if package not installed (#610) Valeriu Predoi
- Pin flake8<3.8.0 (#623) Valeriu Predoi
- Log warnings for likely errors in provenance record (#592) Bouwe Andela
- Unpin flake8 (#646) Bouwe Andela
- More flexible native6 default DRS (#645) Bouwe Andela
- Try to use the same python for running diagnostics as for esmvaltool (#656) Bouwe Andela
- Fix test for lower python version and add note on lxml (#659) Valeriu Predoi
- Added 1m deep average soil moisture variable (#664) bascrezee
- Update docker recipe (#603) Javier Vegas-Regidor
- Improve command line interface (#605) Javier Vegas-Regidor
- Remove utils directory (#697) Bouwe Andela
- Avoid pytest version that crashes (#707) Bouwe Andela
- Options arg in read_config_user_file now optional (#716) Javier Vegas-Regidor
- Produce a readable warning if ancestors are a string instead of a list. (#711) katjaweigel
- Pin Yamale to v2 (#718) Bouwe Andela
- Expanded cmor public API (#714) Manuel Schlund

23.4 Fixes for datasets

- Added various fixes for hybrid height coordinates (#562) Manuel Schlund
- Extended fix for cl-like variables of CESM2 models (#604) Manuel Schlund
- Added fix to convert "geopotential" to "geopotential height" for ERA5 (#640) Evgenia Galytska
- Do not fix longitude values if they are too far from valid range (#636) Javier Vegas-Regidor

23.5 Preprocessor

- Implemented concatenation of cubes with derived coordinates (#546) Manuel Schlund
- Fix derived variable ctotal calculation depending on project and standard name (#620) Valeriu Predoi
- State of the art FX variables handling without preprocessing (#557) Valeriu Predoi
- Add max, min and std operators to multimodel (#602) Javier Vegas-Regidor
- Added preprocessor to extract amplitude of cycles (#597) Manuel Schlund
- Overhaul concatenation and allow for correct concatenation of multiple overlapping datasets (#615) Valeriu Predoi
- Change volume stats to handle and output masked array result (#618) Valeriu Predoi
- Area_weights for cordex in area_statistics (#631) mwjury
- Accept cubes as input in multimodel (#637) sloosvel
- Make multimodel work correctly with yearly data (#677) Valeriu Predoi
- Optimize time weights in time preprocessor for climate statistics (#684) Valeriu Predoi
- Add percentiles to multi-model stats (#679) Peter Kalverla

CHAPTER

TWENTYFOUR

V2.0.0B9

This release includes

24.1 Bug fixes

• Cast dtype float32 to output from zonal and meridional area preprocessors (#581) Valeriu Predoi

24.2 Improvements

- Unpin on Python<3.8 for conda package (run) (#570) Valeriu Predoi
- Update pytest installation marker (#572) Bouwe Andela
- Remove vmrh2o (#573) Mattia Righi
- Restructure documentation (#575) Bouwe Andela
- Fix mask in land variables for CCSM4 (#579) Klaus Zimmermann
- Fix derive scripts wrt required method (#585) Klaus Zimmermann
- · Check coordinates do not have repeated standard names (#558) Javier Vegas-Regidor
- Added derivation script for co2s (#587) Manuel Schlund
- Adapted custom co2s table to match CMIP6 version (#588) Manuel Schlund
- Increase version to v2.0.0b9 (#593) Bouwe Andela
- Add a method to save citation information (#402) SarahAlidoost

For older releases, see the release notes on https://github.com/ESMValGroup/ESMValCore/releases.
